#### Abstract

In this paper we elaborate on the implicit shifted QR eigenvalue algorithm given in [D. A. Bini, P. Boito, Y. Eidelman, L. Gemignani, I. Gohberg, Linear Algebra Appl. 432 (2010), 2006-2031]. The algorithm is substantially simplified and speeded up while preserving its numerical robustness. This allows us to obtain a potentially important advance towards a proof of its backward stability together with both cost reductions and implementative benefits.

AMS classification: 65F15
Keywords: Companion matrix, polynomial roots, quasiseparable matrices, QR method, eigenvalue computation.

## 1. Introduction

The paper is motivated by the search of efficient and numerically robust methods for computing the complete set of eigenvalues of a companion matrix with application to the polynomial zero-finding problem. It is well

[^0]known that for a Hermitian tridiagonal matrix the QR eigenvalue algorithm computes all the eigenvalues at a quadratic cost instead of the cubic cost required for dense Hessenbergs. Recent efforts have reached similar speed-up for certain classes of rank-structured matrices including small rank corrections of Hermitian and unitary matrices (see for a short summary [5] and the references given therein). The study of companion matrices started with the paper [3] by showing that the shifted QR iteration applied to a companion matrix $A \in \mathbb{C}^{N \times N}$ maintains the low rank structure of $A$. From then, a lot of algorithms have been developed that differ on the way used to parameterize and represent the rank structure. An up-to-date survey of these developments and algorithms can be found in the monograph [7].

The choice of the parametrization affects the computational and numerical properties of the resulting eigensolver. From one hand, for accuracy reasons it is important to control the growth of the parameters involved in the QR process by preserving at the same time the unitary plus rank-one structure of the initial companion matrix. These arguments strongly push in favor of the use of unitary-based parametrizations, where most of the coefficients are deduced from the representation of the rank structure in terms of unitary matrices. On the other hand, these parametrizations demand heavy computational effort, resulting in a increase of the big-O constant, and somewhat mask the original QR method, especially because the matrices generated under the process are only implicitly specified in terms of certain additional factors.

One way to alleviate this dichotomy is exploited in the implicit shifted QR eigenvalue algorithm for companion matrices described in our previous work [1]. That algorithm makes use of two different representations for specifying the matrices $A_{k}, k \geq 0, A_{0}=A$ generated under the QR iteration and for carrying out each QR step $A_{k} \rightarrow A_{k+1}$. The composite scheme can be summarized as follows. The matrix $A_{k}$ is initially provided as a rank-one perturbation of a unitary matrix given as product of two banded unitary matrices. These unitary factors are stored in factored form by the product of a linear number of $2 \times 2$ and $3 \times 3$ unitary matrices. Then, from the factorization of the unitary term an explicit entry-wise representation via generators is computed for the cumulative matrix $A_{k}$. This representation is employed to perform one step of the implicit shifted QR eigenvalue algorithm $A_{k} \rightarrow A_{k+1}$, where $A_{k+1}=\mathcal{G}_{N-1} \cdots \mathcal{G}_{1} \cdot A_{k} \cdot \mathcal{G}_{1}^{H} \cdots \mathcal{G}_{N-1}^{H}$ and $\mathcal{G}_{1}, \ldots, \mathcal{G}_{N-1}$ are the unitary transformations generated by the implicit shifted QR iteration. Finally these transformations are applied to the matrix $A_{k}$ represented in the
initial unitary plus rank-one format to obtain the novel subsequent iterate.
Although the numerical experience reported in [1] is satisfactory in terms of accuracy and timings, it would be noted that the proposed approach can be prone to some drawbacks. In particular, the mechanism using two diverse representations is mathematically unsound, it makes difficult to prove theoretical stability results and, even more important, it is computationally burdensome to replicate for possible generalizations and extensions involving both companion pencils and matrix polynomials and block companion matrices. The main contribution of this paper is a substantial improvement of the implicit shifted QR eigenvalue algorithm presented [1] aimed to circumvent all these issues.

More specifically, in this paper the structured QR iteration is greatly simplified by adopting a unique generator-based representation for all the matrices involved in the QR step. A technique named compression is introduced which makes possible to compute the generators of the novel iterate $A_{k+1}$ given the generators of the actual matrix $A_{k}$ together with the transformations (Givens rotation matrices) generated by the implicit shifted QR scheme and with preservation of small orders of generators. The use of a unique parameterization is a potentially important advance towards the proof of the backward stability of the method. The compression process employes unitary matrices and yields a set of generators that are parts of unitary matrices so that the stability properties of the method in [1] are preserved or even enhanced. In addition, the resulting strategy has several computational benefits as it is cheaper, much simpler for implementation and easy to adjust for the block and the pencil case. The results of extensive numerical experiments are reported to confirm the practical impact and significance of these achievements.

The paper is organized as follows. In Sect. 2 we recall the structural properties and introduce condensed representations for the matrices generated by the QR process applied to an input companion matrix. In Sect. 3 we introduce the compression technique. Fast algorithms using this technique that carry out both the single-shift and the double-shift implicit QR iteration are described in Sect. 4 and Sect. 5. In Sect. 6 the results of extensive numerical experiments are reported and, finally, the conclusion and a discussion of future work are the subjects of Sect. 7.

## 2. Definitions and Properties of Generators

For a given monic polynomial $p(z)$ of degree $N, p(z)=\sum_{i=0}^{N-1} p_{i} z^{i}+z^{N}$, the associated companion matrix $A \in \mathbb{C}^{N \times N}$ is

$$
A=\left(\begin{array}{ccccc}
0 & 0 & \ldots & 0 & -p_{0}  \tag{2.1}\\
1 & 0 & \ldots & 0 & -p_{1} \\
0 & 0 & \ldots & 0 & -p_{2} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \ldots & 1 & -p_{N-1}
\end{array}\right)
$$

This paper is concerned with the problem of computing all the eigenvalues of $A$ by means of the implicit shifted QR method

$$
\begin{align*}
& A_{0}=A \\
& q_{k}\left(A^{(k)}\right)=Q^{(k)} R^{(k)},(\text { QR factorization })  \tag{2.2}\\
& A^{(k+1)}:=Q^{(k)^{*}} A^{(k)} Q^{(k)}
\end{align*}
$$

where $q_{k}(z)$ is a monic polynomial of degree one (single-shift step) or two (double-shift step) suitably chosen to accelerate the convergence.

In order to analyze the structural properties of the matrices $A_{k}, k \geq 0$, it is useful to embed $A=A_{0}$ into a larger set. We denote by $\mathcal{H}_{N}$ the class of upper Hessenberg matrices $A \in \mathbb{C}^{N \times N}$ which are rank one perturbations of unitary matrices, i.e.

$$
\begin{equation*}
A=U-p q^{T} \tag{2.3}
\end{equation*}
$$

where $U \in \mathbb{C}^{N \times N}$ is unitary and $p, q \in \mathbb{C}^{N}$. The vectors $p=(p(i))_{i=1}^{N}, q=$ $(q(i))_{i=1}^{N}$ are called the vectors of perturbation for the matrix $A$.

The class $\mathcal{H}_{N}$ contains companion matrices of order $N$. In fact in the representation (2.3) for the companion matrix (2.1) the unitary matrix $U$ can be taken as the circulant

$$
U=\left(\begin{array}{ccccc}
0 & 0 & \ldots & 0 & 1  \tag{2.4}\\
1 & 0 & \ldots & 0 & 0 \\
0 & 1 & 0 & \ldots & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \ldots & 1 & 0
\end{array}\right)
$$

and the vectors of perturbation are

$$
p=\left(\begin{array}{c}
1+p_{0}  \tag{2.5}\\
p_{1} \\
p_{2} \\
\vdots \\
p_{n-1}
\end{array}\right), \quad q=\left(\begin{array}{c}
0 \\
0 \\
0 \\
\vdots \\
1
\end{array}\right) .
$$

Since a matrix $A \in \mathcal{H}_{N}$ is upper Hessenberg, from (2.3) it follows that the entries below the first subdiagonal of the matrix $U$ have the form

$$
\begin{equation*}
U(i, j)=p(i) q(j), \quad 1 \leq j \leq i-2,3 \leq i \leq N . \tag{2.6}
\end{equation*}
$$

We define the class $\mathcal{U}_{N}$ to be the set of $N \times N$ unitary matrices with the elements located in the lower triangular portion specified by $i-j \geq 2,1 \leq$ $i, j \leq N$, of the form (2.6). The numbers $p(i)(i=3, \ldots, N), q(j)(j=$ $1, \ldots, N-2$ ) are called lower generators of the matrix $U$. Notice that (2.6) implies

$$
\begin{equation*}
U(k, 1: k-2)=p(k) Q_{k-2}, \quad k=3, \ldots, N \tag{2.7}
\end{equation*}
$$

with

$$
Q_{j}=\left(\begin{array}{lll}
q(1) & \ldots & q(j) \tag{2.8}
\end{array}\right), \quad j=1, \ldots, N-2 .
$$

We write

$$
Q_{j}=\operatorname{row}(q(i))_{i=1}^{j}, \quad j=1, \ldots, N-2
$$

to denote the matrix formed by appending (scalar) column vectors. Similarly, we use the notatation $\operatorname{col}(\cdot)$ for the matrix obtained by stacking row vectors.

Assume that $U \in \mathbb{C}^{N \times N}$ has entries in the upper triangular part represented in the form

$$
\begin{equation*}
U(i, j)=g(i) b_{i-1, j}^{<} h(j), \quad 1 \leq i \leq j \leq N, \tag{2.9}
\end{equation*}
$$

where $b_{i-1, j}^{<}=b(i) \cdots b(j-1)$ for $i<j$ and $b_{i-1, i}^{<}=I_{r_{i}}$ with matrices $g(i), h(i)(i=1, \ldots, N), b(k)(k=1, \ldots, N-1)$ of sizes $1 \times r_{i}, r_{i} \times 1, r_{k} \times r_{k+1}$ respectively. The elements $g(i), h(i)(i=1, \ldots, N), b(k)(k=1, \ldots, N-1)$ are called upper triangular generators of the matrix $U$ with orders $r_{k}(k=$ $1, \ldots, N)$.

Every matrix $U$ from the class $\mathcal{U}_{N}$ has upper triangular generators with orders not greater than two (see [1] for the proof). Hence, every matrix $A$ from the class $\mathcal{H}_{N}$ defined in (2.3) is completely specified by the following parameters:

1. upper triangular generators $g(i), h(i)(i=1, \ldots, N), b(k)(k=1, \ldots, N-$ 1) of the unitary matrix $U$;
2. subdiagonal entries $\sigma_{k}(k=1, \ldots, N-1)$ of the matrix $U$;
3. the vectors of perturbation $p=(p(i))_{i=1}^{N}, q=(q(i))_{i=1}^{N}$.

For the companion matrix $A$ in (2.1) the subdiagonal entries are $\sigma_{k}=$ $1, k=1, \ldots, N-1$, the vectors of perturbation are defined in (2.5) and upper triangular generators of the unitary matrix $U$ from (2.4) are

$$
\begin{gathered}
g(1)=1, g(i)=0, i=2, \ldots, N, \quad h(j)=0, j=1, \ldots, N-1, h(N)=1, \\
b(k)=1, k=1, \ldots, N-1 .
\end{gathered}
$$

Upper triangular generators of a matrix are however not unique. Thus we conclude by mentioning some basic properties of generators which will be used in the next section to derive a minimal set of upper generators of a matrix $U \in \mathcal{U}_{N}$ and, a fortiori, of a matrix $A \in \mathcal{H}_{N}$.

Lemma 2.1. Let $U \in \mathbb{C}^{N \times N}$ be a matrix with upper triangular generators $g(i), h(i)(i=1, \ldots, N), \quad b(k)(k=1, \ldots, N-1)$ with orders $r_{k}(k=$ $1, \ldots, N)$. Using these generators define the matrices $G_{k}, H_{k}$ of sizes $k \times$ $r_{k}, r_{k} \times(N-k+1)$, respectively, via the recursive relations

$$
\begin{equation*}
G_{1}=g(1), \quad G_{k}=\binom{G_{k-1} b(k-1)}{g(k)}, k=2, \ldots, N \tag{2.10}
\end{equation*}
$$

and

$$
\begin{equation*}
H_{N}=h(N), \quad H_{k}=\binom{h(k)}{b(k) H_{k+1}}, k=N-1, \ldots, 1 . \tag{2.11}
\end{equation*}
$$

Then the relations

$$
\begin{equation*}
U(i, i: N)=g(i) H_{i}, \quad i=1, \ldots, N \tag{2.12}
\end{equation*}
$$

and

$$
\begin{equation*}
U(1: i, i)=G_{i} h(i), \quad i=1, \ldots, N \tag{2.13}
\end{equation*}
$$

hold.
Proof. The recursions (2.12) and (2.13) mean

$$
\begin{equation*}
G_{i}=\operatorname{col}\left(g(k) b_{k-1, i}^{<} i_{k=1}^{i}, \quad i=1, \ldots, N\right. \tag{2.14}
\end{equation*}
$$

and

$$
\begin{equation*}
H_{j}=\operatorname{row}\left(b_{k, j+1}^{く} h(k)\right)_{k=j}^{N} . \tag{2.15}
\end{equation*}
$$

By comparing (2.14) and (2.15) with (2.9) we obtain (2.12) and (2.13).
The reverse statement is also true. The proof immediately follows from (2.14) and (2.13).

Lemma 2.2. Let $U \in \mathbb{C}^{N \times N}$ be matrix satisfying the relations (2.13), where $G_{k}(k=1, \ldots, N)$ are matrices defined via the relations (2.10) for some matrices $g(i), h(i)(i=1, \ldots, N), b(k)(k=2, \ldots, N-1)$. Then the elements $g(i), h(i)(i=1, \ldots, N), b(k)(k=1, \ldots, N-1)$ are upper triangular generators of the matrix $U$.

The next result describes a procedure which can be used to modify a set of generators by computing a possibly different set of generators of lower orders.

Lemma 2.3. Let $U \in \mathbb{C}^{N \times N}$ be a matrix with upper triangular generators $g(i), h(i)(i=1, \ldots, N), b(k)(k=2, \ldots, N-1)$ of orders $r_{k}(k=1, \ldots, N)$. By using the generators $g(k), b(k)$ define the matrices $G_{k}(k=1, \ldots, N-1)$ via relations (2.10). Suppose that for matrices $S_{k}(k=1, \ldots, N)$ of sizes $r_{k} \times t_{k}$ and matrices $g^{(1)}(i), h^{(1)}(i)(i=1, \ldots, N), b^{(1)}(k)(k=1, \ldots, N-1)$ with corresponding sizes the relations

$$
\begin{align*}
& g^{(1)}(k)=g(k) S_{k}, \quad k=1, \ldots, N,  \tag{2.16}\\
& G_{k} S_{k} b^{(1)}(k)=G_{k} b(k) S_{k+1}, \quad k=1, \ldots, N-1,  \tag{2.17}\\
& G_{k} S_{k} h^{(1)}(k)=G_{k} h(k), \quad k=1, \ldots, N \tag{2.18}
\end{align*}
$$

are satisfied. Then the elements $g^{(1)}(i), h^{(1)}(i)(i=1, \ldots, N), b^{(1)}(k)(k=$ $1, \ldots, N-1)$ are upper triangular generators of the matrix $U$ of the orders $t_{k}(k=1, \ldots, N)$.

Proof. Define the matrices $G_{k}^{(1)}$ of sizes $k \times t_{k}$ via the recursive relations

$$
\begin{equation*}
G_{1}^{(1)}=g^{(1)}(1), \quad G_{k}^{(1)}=\binom{G_{k-1}^{(1)} b^{(1)}(k-1)}{g^{(1)}(k)}, k=2, \ldots, N . \tag{2.19}
\end{equation*}
$$

We prove by induction the relations

$$
\begin{equation*}
G_{k}^{(1)}=G_{k} S_{k}, \quad k=1, \ldots, N . \tag{2.20}
\end{equation*}
$$

For $k=1$ from (2.19), (2.10) and (2.16) we get

$$
G_{1}^{(1)}=g^{(1)}(1)=g(1) S_{1}=G_{1} S_{1} .
$$

Let us now assume that for some $k$ with $1 \leq k \leq N-1$ the relation (2.20) holds. From (2.19), (2.16), (2.17) and (2.10) we find that

$$
\begin{aligned}
& G_{k+1}^{(1)}=\binom{G_{k}^{(1)} b^{(1)}(k)}{g^{(1)}(k+1)}= \\
& \binom{G_{k} S_{k} b^{(1)}(k)}{g(k+1) S_{k+1}}=\binom{G_{k} b(k) S_{k+1}}{g(k+1) S_{k+1}}=G_{k+1} S_{k+1},
\end{aligned}
$$

which completes the proof of (2.20). By using (2.18) and (2.20) we obtain

$$
G_{k}^{(1)} h^{(1)}(k)=G_{k} S_{k} h^{(1)}(k)=G_{k} h(k), \quad k=1, \ldots, N .
$$

Hence by Lemma 2.1 it follows that

$$
U(1: k, k)=G_{k}^{(1)} h^{(1)}(k), \quad k=1, \ldots, N
$$

and by Lemma 2.2 we conclude that $g^{(1)}(i), h^{(1)}(i)(i=1, \ldots, N), b^{(1)}(k)(k=$ $1, \ldots, N-1)$ are upper triangular generators of the matrix $U$.

## 3. The Compression Technique

Based on Lemma 2.3, in this section we introduce a novel method, referred to as the compression technique, that for any matrix from the class $\mathcal{U}_{N}$ with given upper triangular generators computes another set of generators with minimal orders. This method is at the core of the fast QR eigenvalue algorithm for companion matrices developed in the next two sections.

Theorem 3.1. Let $U \in \mathbb{C}^{N \times N}$ be a unitary matrix from the class $\mathcal{U}_{N}$ with lower generators $p(i)(i=3, \ldots, N), q(j)(j=1, \ldots, N-2)$, subdiagonal entries $\sigma_{k}(k=1, \ldots, N-1)$, upper triangular generators $g(i), h(i)(i=$ $1, \ldots, N), b(k)(k=1, \ldots, N-1)$ of orders $r_{k}(k=1, \ldots, N)$. Then $a$ set of upper triangular generators $g^{(1)}(i), h^{(1)}(i)(i=1, \ldots, N), b^{(1)}(k)(k=$ $1, \ldots, N-1$ ) of the matrix $U$ of orders

$$
\begin{equation*}
t_{k}=2, k=1, \ldots, N-1, \quad t_{N}=1 \tag{3.1}
\end{equation*}
$$

are obtained by using the following algorithm.

1. Set

$$
\begin{equation*}
S_{N}=h(N), \quad h^{(1)}(N)=1, \quad g^{(1)}(N)=g(N) S_{N} \tag{3.2}
\end{equation*}
$$

and

$$
\begin{gather*}
h^{(1)}(N-1)=\binom{1}{0}, b^{(1)}(N-1)=\binom{0}{1},  \tag{3.3}\\
S_{N-1}=\left(h(N-1) \quad b(N-1) S_{N}\right),  \tag{3.4}\\
g^{(1)}(N-1)=g(N-1) S_{N-1},  \tag{3.5}\\
z_{N}=\left(\begin{array}{ll}
\sigma_{N-1} & \left.g^{(1)}(N)\right), \quad x_{N}=p(N) .
\end{array} . . \begin{array}{l} 
\\
\hline
\end{array}\right) . \tag{3.6}
\end{gather*}
$$

2. For $k=N-1, \ldots, 2$ perform the following.
(a) Determine the complex Givens rotation $V_{k}$ and the number $x_{k}$ such that

$$
\begin{equation*}
\binom{p(k)}{x_{k+1}}=V_{k}\binom{x_{k}}{0} . \tag{3.7}
\end{equation*}
$$

(b) Compute

$$
\left(\begin{array}{cc}
a_{k} & y_{k}  \tag{3.8}\\
f_{k} & d_{k}
\end{array}\right)=V_{k}^{*}\left(\begin{array}{cc}
\sigma_{k-1} & g^{(1)}(k) \\
x_{k+1} q(k-1) & z_{k+1}
\end{array}\right)
$$

with the matrices $a_{k}, y_{k}, f_{k}, d_{k}, z_{k+1}$ of sizes $1 \times 1,1 \times 2,1 \times 1,1 \times$ $2,1 \times 2$ respectively. It is shown that the vector row $\left(\begin{array}{cc}f_{k} & d_{k}\end{array}\right)$ has unit norm so that one can determine a $3 \times 3$ unitary matrix $F_{k-1}$ satisfying the condition

$$
\left(\begin{array}{ll}
f_{k} & d_{k}
\end{array}\right) F_{k-1}^{*}=\left(\begin{array}{ll}
0_{1 \times 2} & 1 \tag{3.9}
\end{array}\right) .
$$

(c) Determine the matrices $h^{(1)}(k-1), b^{(1)}(k-1)$ of sizes $2 \times 1,2 \times 2$ from the partition

$$
\begin{equation*}
F_{k-1}(1: 2,:)=\left(h^{(1)}(k-1) \quad b^{(1)}(k-1)\right) . \tag{3.10}
\end{equation*}
$$

(d) Compute the matrices $S_{k-1}$ of the size $r_{k-1} \times 2$ and $z_{k}$ of the size $1 \times 2$ by the formulas

$$
\begin{align*}
& S_{k-1}=h(k-1)\left(h^{(1)}(k-1)\right)^{*}+b(k-1) S_{k}\left(b^{(1)}(k-1)\right)^{*}, \\
& z_{k}=a_{k}\left(h^{(1)}(k-1)\right)^{*}+y_{k}\left(b^{(1)}(k-1)\right)^{*} . \tag{3.11}
\end{align*}
$$

(e) Compute

$$
\begin{equation*}
g^{(1)}(k-1)=g(k-1) S_{k-1} . \tag{3.12}
\end{equation*}
$$

Proof. One should check that the relations (2.16), (2.17), (2.18) hold; hence, by Lemma 2.3 this implies that $g^{(1)}(i), h^{(1)}(i)(i=1, \ldots, N)$, and $b^{(1)}(k)(k=1, \ldots, N-1)$ are upper triangular generators of the matrix $U$. Moreover from the formulas (3.2), (3.3), (3.10), (3.12) it follows that the orders of these generators are in accordance with (3.1).

From (3.2) we obtain (2.18) and (2.16) with $k=N$. By using (3.3), (3.5), (3.4) we obtain (2.16), (2.17), (2.18) with $k=N-1$.

Next we prove by induction that all the matrices

$$
\hat{U}_{k}=\left(\begin{array}{cc}
U(1: k, 1: k-1) & G_{k} S_{k}  \tag{3.13}\\
x_{k+1} Q_{k-1} & z_{k+1}
\end{array}\right), \quad k=2, \ldots, N-1
$$

are unitary, the rows $\left(f_{k} d_{k}\right)(k=N, \ldots, 2)$ have unit norms and the relations (2.16), (2.17), (2.18) hold.

Using (3.6) and (3.4) we have

$$
\hat{U}_{N-1}=\left(\begin{array}{ccc}
U(1: N-1,1: N-2) & G_{N-1} h(N-1) & G_{N-1} b(N-1) h(N) \\
p(N) Q_{N-2} & \sigma_{N-1} & g(N) h(N)
\end{array}\right) .
$$

By using (2.7) with $k=N$, (2.13) with $i=N-1, N$ and (2.10) with $k=N$ we deduce that $\hat{U}_{N-1}=U$ and hence $\hat{U}_{N-1}$ is a unitary matrix. Suppose that for some $k$ with $N-1 \geq k \geq 2$ the matrix $\hat{U}_{k}$ is unitary. By using (2.7), (2.13), (2.10) and the equality $Q_{k-1}=\left(\begin{array}{ll}Q_{k-2} & q(k-1)\end{array}\right)$ we get

$$
\hat{U}_{k}=\left(\begin{array}{ccc}
U(1: k-1,1: k-2) & G_{k-1} h(k-1) & G_{k-1} b(k-1) S_{k} \\
p(k) Q_{k-2} & \sigma_{k-1} & g(k) S_{k} \\
x_{k+1} Q_{k-2} & x_{k+1} q(k-1) & z_{k+1}
\end{array}\right)
$$

From the equalities (3.7), (3.8) and (3.5), (3.12) we obtain

$$
\begin{align*}
& \left(\begin{array}{cc}
I_{k-1} & 0 \\
0 & V_{k}^{*}
\end{array}\right) \hat{U}_{k}= \\
& \left(\begin{array}{ccc}
U(1: k-1,1: k-2) & G_{k-1} h(k-1) & G_{k-1} b(k-1) S_{k} \\
x_{k} Q_{k-2} & a_{k} & y_{k} \\
0_{1 \times(k-2)} & f_{k} & d_{k}
\end{array}\right) . \tag{3.14}
\end{align*}
$$

Since the matrix on the left hand side of (3.14) is unitary the three-dimensional row ( $\begin{array}{ll}f_{k} & d_{k}\end{array}$ ) has the unit norm. Hence one can determine a unitary $3 \times 3$ matrix $F_{k-1}$ such that (3.9) holds. Further, from (3.10) we have

$$
\left(\begin{array}{cc}
h(k-1) & b(k-1) S_{k}  \tag{3.15}\\
a_{k} & y_{k}
\end{array}\right) F_{k-1}^{*}=\left(\begin{array}{cc}
S_{k-1} & w_{k}^{\prime} \\
z_{k} & w_{k}^{\prime \prime}
\end{array}\right)
$$

with the matrices $S_{k-1}, z_{k}$ of sizes $r_{k-1} \times 2,1 \times 2$ determined via (3.11) and some matrices $w_{k}^{\prime}, w_{k}^{\prime \prime}$ of sizes $r_{k-1} \times 1,1 \times 1$. Thus by using (3.14), (3.9) and (3.15) we get

Since the matrix on the left hand side of (3.16) is unitary we conclude that $G_{k-1} w_{k}^{\prime}=0, w_{k}^{\prime \prime}=0$ and, therefore,

$$
\begin{gathered}
\left(\begin{array}{cc}
I_{k-1} & 0 \\
0 & V_{k}^{*}
\end{array}\right) \hat{U}_{k}\left(\begin{array}{cc}
I_{k-2} & 0 \\
0 & F_{k-1}^{*}
\end{array}\right)= \\
\left(\begin{array}{ccc}
U(1: k-1,1: k-2) & G_{k-1} S_{k-1} & 0 \\
x_{k} Q_{k-2} & z_{k} & 0 \\
0 & 0 & 1
\end{array}\right)=\left(\begin{array}{cc}
\hat{U}_{k-1} & 0 \\
0 & 1
\end{array}\right) .
\end{gathered}
$$

Hence it follows that the matrix $\hat{U}_{k-1}$ is unitary. Moreover from (3.15) it follows that

$$
\left(h(k-1) \quad b(k-1) S_{k}\right) F_{k-1}^{*}=\left(\begin{array}{cc}
S_{k-1} & w_{k}^{\prime}
\end{array}\right)
$$

and due to $G_{k-1} w_{k}^{\prime}=0$ we obtain

$$
\left(G_{k-1} h(k-1) \quad G_{k-1} b(k-1) S_{k}\right)=\left(\begin{array}{ll}
G_{k-1} S_{k-1} & 0 \tag{3.17}
\end{array}\right) F_{k-1}
$$

Finally, from (3.17) using the partition (3.10) we obtain the equalities (2.17), (2.18) with $k=N-2, \ldots, 1$. The relations (2.16) with $k=N-$ $2, \ldots, 1$ follow directly from (3.12).

It is worth noting that the representation of a matrix $U$ from the class $\mathcal{U}_{N}$ by means of a set of upper generators of minimal orders constructed as in the proof of Theorem 3.1 can be related with a suitable factorization of $U$ exploited for the design of the QR algorithm suggested in [1].

Remark 3.2. From the proof of Theorem 3.1 one can derive easily that every matrix $U$ from the class $\mathcal{U}_{N}$ admits the factorization

$$
U=V \cdot F,
$$

where

$$
\begin{aligned}
V=\tilde{V}_{N-1} \cdots \tilde{V}_{2}, & F=\tilde{F}_{1} \cdots \tilde{F}_{N-2} \\
\tilde{V}_{i}=I_{i-1} \oplus V_{i} \oplus I_{N-i-1}, & \tilde{F}_{i}=I_{i-1} \oplus F_{i} \oplus I_{N-i-2}
\end{aligned}
$$

with $2 \times 2$ unitary matrices $V_{i}$ and $3 \times 3$ unitary matrices $F_{i}$ defined in the theorem.

## 4. The Structured QR Iteration: The Single-Shift Case

Let $A \in \mathbb{C}^{N \times N}$ be an upper Hessenberg matrix. Let us consider one single-shift step of the $Q R$ iteration (2.2) for this matrix with shift polynomial $q(z)=z-\alpha$. The implicit QR algorithm consists of the computation of the unitary matrix $Q$ of the form

$$
\begin{equation*}
Q=\tilde{Q}_{1} \tilde{Q}_{2} \cdots \tilde{Q}_{N-1} \tag{4.1}
\end{equation*}
$$

where

$$
\begin{equation*}
\tilde{Q}_{i}=I_{i-1} \oplus Q_{i} \oplus I_{N-i-1} \tag{4.2}
\end{equation*}
$$

and $Q_{i}, i=1, \ldots, N-1$ are complex Givens rotation matrices determined so that $\left(\tilde{Q}_{1}^{*} q(A)\right)(2,1)=0$ and, moreover, $A^{(1)}=Q^{*} A Q$ is upper Hessenberg.

The restoration of the Hessenberg form is performed by means of a bulgechasing procedure. First we compute the matrices $A_{1}^{\prime}=\tilde{Q}_{1}^{*} A, A_{1}=A_{1}^{\prime} \tilde{Q}_{1}$. Then we observe that the matrix $A_{1}^{\prime}$ is upper Hessenberg and the matrix $A_{1}$ is similar to the matrix $A$ and contains a nonzero entry in the $(3,1)$ position. We choose the matrix $Q_{2}$ in order to annihilate this entry, i.e. to get $\left(\tilde{Q}_{2}^{*} A_{1}\right)(3,1)=0$. Then we compute the matrices $A_{2}^{\prime}=\tilde{Q}_{2}^{*} A_{1}, A_{2}=A_{2}^{\prime} \tilde{Q}_{2}$, the matrix $A_{2}^{\prime}$ is upper Hessenberg and the matrix $A_{2}$ is similar to the matrix $A$ and contains a nonzero entry in the $(4,2)$ position. We choose the matrix $Q_{3}$ in order to annihilate this entry, i.e. to get $\left(\tilde{Q}_{3}^{*} A_{2}\right)(4,2)=0$. Then we compute the matrices $A_{3}^{\prime}=\tilde{Q}_{3}^{*} A_{2}, A_{3}=A_{3}^{\prime} \tilde{Q}_{3}$, the matrix $A_{3}^{\prime}$ is upper Hessenberg and the matrix $A_{3}$ is similar to the matrix $A$ and contains a nonzero entry in the $(5,3)$ position. We continue this procedure and obtain the sequence of matrices

$$
\begin{equation*}
A_{0}=A ; A_{k}^{\prime}=\tilde{Q}_{k}^{*} A_{k-1}, A_{k}=A_{k}^{\prime} \tilde{Q}_{k}, k=1, \ldots, N-1 ; A^{(1)}:=A_{N-1} \tag{4.3}
\end{equation*}
$$

Here all the matrices $A_{k}^{\prime}, k=1, \ldots, N-1$, and the matrix $A^{(1)}$ are upper Hessenberg and all the matrices $A_{k}, k=1, \ldots, N-1$, are similar to the matrix $A$.

In the sequel of this section we present a fast adaptation of the implicit single-shift QR algorithm for an input matrix $A \in \mathcal{H}_{N}$. The modified algorithm works on the generators of the matrix and this explains why it is referred to as a structured QR iteration.

Using the decomposition (2.3) and setting

$$
\begin{gather*}
U_{0}=U ; U_{k}^{\prime}=\tilde{Q}_{k}^{*} U_{k-1}, U_{k}=U_{k}^{\prime} \tilde{Q}_{k}, k=1, \ldots, N-1 ; U^{(1)}:=U_{N-1},  \tag{4.4}\\
p_{0}=p ; p_{k}=\tilde{Q}_{k}^{*} p_{k-1}, k=1, \ldots, N-1 ; p^{(1)}:=p_{N-1}  \tag{4.5}\\
q_{0}=q ; q_{k}=\tilde{Q}_{k}^{T} q_{k}, k=1, \ldots, N-1 ; q^{(1)}:=q_{N-1} . \tag{4.6}
\end{gather*}
$$

we get

$$
\begin{equation*}
A_{k}^{\prime}=U_{k}^{\prime}-p_{k} q_{k-1}^{T}, \quad A_{k}=U_{k}-p_{k} q_{k}^{T}, \quad k=1, \ldots, N-1 . \tag{4.7}
\end{equation*}
$$

Here $U_{k}, U_{k}^{\prime}$ are unitary matrices and $p_{k}, q_{k}$ are vectors. The new iterant $A^{(1)}$ has therefore the form

$$
\begin{equation*}
A^{(1)}=U^{(1)}-p^{(1)}\left(q^{(1)}\right)^{T} . \tag{4.8}
\end{equation*}
$$

The problem of computing a set of generators of the matrix $A^{(1)}$ is addressed in the following result.

Theorem 4.1. Let $A=U-p q^{T}$ be a matrix from the class $\mathcal{H}_{N}$ with vectors of perturbation $p=\operatorname{col}(p(i))_{i=1}^{N}, q=\operatorname{col}(q(i))_{i=1}^{N}$, upper triangular generators $g(i), h(i)(i=1, \ldots, N), b(k)(k=1, \ldots, N-1)$ of orders $r_{k}(k=1, \ldots, N)$ and subdiagonal entries $\sigma_{k}(k=1, \ldots, N-1)$ of the matrix $U$, and let $\alpha$ be a number. Then the Givens rotation matrices $Q_{k}, k=1, \ldots, N-1$, the vectors of perturbation $p^{(1)}=\operatorname{col}\left(p^{(1)}(i)\right)_{i=1}^{N}, q^{(1)}=\operatorname{col}\left(q^{(1)}(i)\right)_{i=1}^{N}$ of the upper Hessenberg matrix $A^{(1)}=Q^{*} A Q$ as well as the subdiagonal entries $\sigma_{k}^{(1)}(k=1, \ldots, N-1)$ and the upper triangular generators $g^{(1)}(i), h^{(1)}(i)(i=$ $1, \ldots, N), b^{(1)}(k)(k=1, \ldots, N-1)$ with orders not greater than two of the unitary matrix $U^{(1)}$ in (4.8) are obtained by the following procedure.

1. Compute the Givens rotation matrices $Q_{k}, k=1, \ldots, N-1$, the vectors of perturbation $p^{(1)}=\operatorname{col}\left(p^{(1)}(i)\right)_{i=1}^{N}, q^{(1)}=\operatorname{col}\left(q^{(1)}(i)\right)_{i=1}^{N}$ of the upper Hessenberg matrix $A^{(1)}=Q^{*} A Q$ and the the subdiagonal entries $\sigma_{k}^{(1)}(k=1, \ldots, N-1)$ of the unitary matrix $U^{(1)}$, by performing these steps.
(a) Determine the complex Givens rotation matrix $Q_{1}$ from the condition

$$
\begin{equation*}
Q_{1}^{*}\binom{g(1) h(1)-p(1) q(1)-\alpha}{\sigma_{1}-p(2) q(1)}=\binom{*}{0} . \tag{4.9}
\end{equation*}
$$

Compute

$$
\begin{gather*}
\left(\begin{array}{ll}
\gamma_{1} & w_{1} \\
f_{2} & v_{2}
\end{array}\right)=Q_{1}^{*}\left(\begin{array}{cc}
g(1) h(1) & g(1) b(1) \\
\sigma_{1} & g(2)
\end{array}\right)  \tag{4.10}\\
\left(\begin{array}{ll}
s_{2} & \eta_{2} \\
\rho_{2} & \beta_{2}
\end{array}\right)=\left(\begin{array}{cc}
f_{2} & v_{2} h(2) \\
p(3) q(1) & \sigma_{2}
\end{array}\right) Q_{1},  \tag{4.11}\\
\binom{p^{(1)}(1)}{c_{2}}=Q_{1}^{*}\binom{p(1)}{p(2)}, \quad\left(\begin{array}{ll}
q^{(1)}(1) & \theta_{2}
\end{array}\right)=\left(\begin{array}{ll}
q(1) & q(2)) Q_{1}
\end{array}\right. \tag{4.12}
\end{gather*}
$$

with numbers $\gamma_{1}, f_{2}, s_{2}, \rho_{2}, \eta_{2}, \beta_{2}, c_{2}, \theta_{2}$ and $r_{2}$-dimensional rows $w_{1}$ and $v_{2}$.
(b) For $k=2, \ldots, N-2$ perform the following computation. Determine the complex Givens rotation matrix $Q_{k}$ and the number $\delta_{k-1}$ such that

$$
\begin{equation*}
Q_{k}^{*}\binom{s_{k}-c_{k} q^{(1)}(k-1)}{\rho_{k}-p(k+1) q^{(1)}(k-1)}=\binom{\delta_{k-1}}{0} . \tag{4.13}
\end{equation*}
$$

Compute

$$
\left.\begin{array}{c}
\left(\begin{array}{cc}
\gamma_{k} & w_{k} \\
f_{k+1} & v_{k+1}
\end{array}\right)=Q_{k}^{*}\left(\begin{array}{cc}
\eta_{k} & v_{k} b(k) \\
\beta_{k} & g(k+1)
\end{array}\right), \\
\left(\begin{array}{cc}
s_{k+1} & \eta_{k+1} \\
\rho_{k+1} & \beta_{k+1}
\end{array}\right)=\left(\begin{array}{cc}
f_{k+1} & v_{k+1} h(k+1) \\
p(k+2) \theta_{k} & \sigma_{k+1}
\end{array}\right) Q_{k}, \\
\binom{p^{(1)}(k)}{c_{k+1}}=Q_{k}^{*}\binom{c_{k}}{p(k+1)}, \\
\left(q^{(1)}(k)\right.
\end{array} \theta_{k+1}\right)=\left(\begin{array}{ll}
\theta_{k} & q(k+1)) Q_{k}, \\
\sigma_{k-1}^{(1)}=\delta_{k-1}+p^{(1)}(k) q^{(1)}(k-1) \tag{4.17}
\end{array}\right.
$$

with numbers $\gamma_{k}, f_{k+1}, s_{k+1}, \rho_{k+1}, \eta_{k+1}, \beta_{k+1}, c_{k+1}, \theta_{k+1}$ and $\quad r_{k+1}-$ dimensional rows $w_{k}, v_{k+1}$.
(c) Determine the complex Givens rotation matrix $Q_{N-1}$ and the number $\delta_{N-2}$ such that

$$
\begin{equation*}
Q_{N-1}^{*}\binom{s_{N-1}-c_{N-1} q^{(1)}(N-2)}{\rho_{N-1}-p(N) q^{(1)}(N-2)}=\binom{\delta_{N-2}}{0} \tag{4.18}
\end{equation*}
$$

Compute

$$
\left.\begin{array}{c}
\left(\begin{array}{cc}
\gamma_{N-1} & w_{N-1} \\
f_{N} & v_{N}
\end{array}\right)=Q_{N-1}^{*}\left(\begin{array}{cc}
\eta_{N-1} & v_{N-1} b(N-1 \\
\beta_{N-1} & g(N)
\end{array}\right), \\
\left(\begin{array}{ll}
s_{N} & \eta_{N}
\end{array}\right)=\left(\begin{array}{ll}
f_{N} & v_{N} h(N)
\end{array}\right) Q_{N-1} \\
\binom{p^{(1)}(N-1)}{p^{(1)}(N)}=Q_{N-1}^{*}\binom{c_{N-1}}{p(N)}, \\
\left(q^{(1)}(N-1)\right.
\end{array} q^{(1)}(N)\right)=\left(\begin{array}{ll}
\theta_{N-1} & q(N)) Q_{N-1} \\
\sigma_{N-2}^{(1)}=\delta_{N-2}+p^{(1)}(N-1) q^{(1)}(N-2) \tag{4.22}
\end{array}\right.
$$

with numbers $\gamma_{N-1}, f_{N}, s_{N}, \eta_{N}$ and $r_{N}$-dimensional rows $w_{N-1}, v_{N}$. Set $\sigma_{N-1}^{(1)}=s_{N}$.
2. Determine the numbers $h_{Q}(k), b_{Q}(k), d_{Q}(k), g_{Q}(k)$ from the partition

$$
Q_{k}=\left(\begin{array}{cc}
h_{Q}(k) & b_{Q}(k)  \tag{4.23}\\
d_{Q}(k) & g_{Q}(k)
\end{array}\right), k=1, \ldots, N-1
$$

and set

$$
\begin{align*}
& g_{U}(k)=\left(\begin{array}{cc}
\gamma_{k} & w_{k}
\end{array}\right), k=1, \ldots, N-1, \quad g_{U}(N)=\eta_{N},  \tag{4.24}\\
& h_{U}(k)=\binom{h_{Q}(k)}{h(k+1) d_{Q}(k)}, k=1, \ldots, N-1, \quad h_{U}(N)=1,  \tag{4.25}\\
& b_{U}(k)=\left(\begin{array}{cc}
b_{Q}(k) & 0 \\
h(k+1) g_{Q}(k) & b(k+1)
\end{array}\right), k=1, \ldots, N-2, \\
& b_{U}(N-1)=\binom{b_{Q}(N-1)}{h(N) g_{Q}(N-1)} . \tag{4.26}
\end{align*}
$$

3. By using the algorithm from Theorem 3.1 with lower generators $p^{(1)}(i)(i=$ $3, \ldots, N), q^{(1)}(j)(j=1, \ldots, N-2)$, subdiagonal entries $\sigma_{k}^{(1)}(k=$ $1, \ldots, N-1)$ and upper triangular generators $g_{U}(i), h_{U}(i)(i=1, \ldots, N)$, and $b_{U}(k)(k=1, \ldots, N-1)$ with orders $r_{k}^{\prime}=r_{k}+1, k=1, \ldots, N-$
$1, r_{N}^{\prime}=1$ determine upper triangular generators $g^{(1)}(i), h^{(1)}(i)(i=$ $1, \ldots, N), b^{(1)}(k)(k=1, \ldots, N-1)$ of orders

$$
\begin{equation*}
t_{k}=2, k=1, \ldots, N-1, \quad t_{N}=1 \tag{4.27}
\end{equation*}
$$

of the matrix $U^{(1)}$.
Proof. From (4.2) it follows that premultiplication of a matrix $C$ by the matrix $\tilde{Q}_{k}^{*}$ means only premultiplication of the rows $k, k+1$ of $C$ by the matrix $Q_{k}^{*}$ and postmultiplication of a matrix $C$ by the matrix $\tilde{Q}_{k}$ means only postmultiplication of the columns $k, k+1$ of $C$ by the matrix $Q_{k}$. This in particular implies that the vectors $p_{k}, q_{k}$ from (4.5), (4.6) have the form

$$
\begin{align*}
p_{k} & =\left(p^{(1)}(1), \ldots, p^{(1)}(k), c_{k+1}, p(k+2), \ldots, p(N)\right)^{T}, & k=1, \ldots, N-2, \\
q_{k} & =\left(q^{(1)}(1), \ldots, q^{(1)}(k), \theta_{k+1}, q(k+2), \ldots, q(N)\right)^{T}, & k=1, \ldots, N-2 \tag{4.28}
\end{align*}
$$

and moreover the formulas (4.12), (4.16), (4.21) yield the coordinates of the vectors of perturbation $p^{(1)}=Q^{*} p, q^{(1)}=Q^{T} q$. Furthermore from (4.4) it follows that

$$
\begin{gather*}
U_{k}^{\prime}(1: k, 1: k-1)=U^{(1)}(1: k, 1: k-1), k=2, \ldots, N-1,  \tag{4.30}\\
U_{k}^{\prime}(k+2: N, k+1: N)=U(k+2: N, k+1: N), k=1, \ldots, N-2 \tag{4.31}
\end{gather*}
$$

and

$$
\begin{equation*}
U_{k}(1: k, 1: k)=U^{(1)}(1: k, 1: k), k=1, \ldots, N-1 . \tag{4.32}
\end{equation*}
$$

By using the matrices $g_{U}(k), b_{U}(k)$ define the matrices $G_{k}^{U}$ via the recursive relations

$$
\begin{equation*}
G_{1}^{U}=g_{U}(1), \quad G_{k}^{U}=\binom{G_{k-1}^{U} b_{U}(k-1)}{g_{U}(k)}, k=2, \ldots, N . \tag{4.33}
\end{equation*}
$$

From (4.24), (4.26) we have

$$
\begin{gather*}
G_{1}^{U}=\left(\begin{array}{ll}
\gamma_{1} & w_{1}
\end{array}\right), \quad G_{k}^{U}=\left(\begin{array}{cc}
G_{k-1}^{U} \tilde{b}(k) & G_{k-1}^{U} \hat{b}(k) \\
\gamma_{k} & w_{k}
\end{array}\right), k=2, \ldots, N-1 \\
G_{N}^{U}=\binom{G_{N-1}^{U} b_{U}(N-1)}{\eta_{N}} \tag{4.34}
\end{gather*}
$$

with

$$
\begin{equation*}
\tilde{b}(k)=\binom{b_{Q}(k-1)}{h(k) g_{Q}(k-1)}, \hat{b}(k)=\binom{0_{1 \times r_{k+1}}}{b(k)}, k=2, \ldots, N-1 . \tag{4.35}
\end{equation*}
$$

Notice that in the view of (4.23) one can rewrite the formulas (4.25), (4.26) for $k=1, \ldots, N-2$ in the form

$$
\left(\begin{array}{ccc}
h_{U}(k) & \tilde{b}(k+1) & \hat{b}(k+1)
\end{array}\right)=\left(\begin{array}{ccc}
1 & 0 & 0  \tag{4.36}\\
0 & h(k+1) & b(k+1)
\end{array}\right)\left(\begin{array}{cc}
Q_{k} & 0 \\
0 & I_{r_{k+2}}
\end{array}\right),
$$

and

$$
\left(h_{U}(N-1) \quad b_{U}(N-1)\right)=\left(\begin{array}{cc}
1 & 0  \tag{4.37}\\
0 & h(N)
\end{array}\right) Q_{N-1} .
$$

We prove by induction that the Givens rotation matrices $Q_{k}$ with $k=$ $1, \ldots, N-2$ are determined via (4.9), (4.13) and, moreover, that the relations

$$
\begin{gather*}
U_{k}(1: k+2, k: N)= \\
\left(\begin{array}{ccc}
G_{k}^{U} h_{U}(k) & G_{k}^{U} \tilde{b}(k+1) & G_{k}^{U} \hat{b}(k+1) H_{k+2} \\
s_{k+1} & \eta_{k+1} & v_{k+1} b(k+1) H_{k+2} \\
\rho_{k+1} & \beta_{k+1} & g(k+2) H_{k+2}
\end{array}\right), \tag{4.38}
\end{gather*}
$$

hold for $k=1, \ldots, N-2$.
From (2.9) and (2.3) we obtain

$$
(A-\alpha I)(1: 2,1)=\binom{g(1) h(1)-p(1) q(1)-\alpha}{\sigma_{1}-p(2) q(1)}
$$

which yields the condition (4.9) for the matrix $Q_{1}$.
By using (2.6) with $i=3, j=1$, (2.12) with $i=1,2,3$ and (2.11) with $k=1,2$ we find that

$$
U(1: 3,1: N)=\left(\begin{array}{ccc}
g(1) h(1) & g(1) b(1) h(2) & g(1) b(1) b(2) H_{3}  \tag{4.39}\\
\sigma_{1} & g(2) h(2) & g(2) b(2) H_{3} \\
p(3) q(1) & \sigma_{2} & g(3) H_{3}
\end{array}\right) .
$$

From (4.10) we get

$$
U_{1}^{\prime}(1: 3,1: N)=\left(\begin{array}{ccc}
\gamma_{1} & w_{1} h(2) & w_{1} b(2) H_{3} \\
f_{2} & v_{2} h(2) & v_{2} b(2) H_{3} \\
p(3) q(1) & \sigma_{2} & g(3) H_{3}
\end{array}\right) .
$$

The first row of the matrix $U_{1}^{\prime}$ can be expressed in the form

$$
U_{1}^{\prime}(1,1: N)=\left(\begin{array}{cc}
\gamma_{1} & w_{1}
\end{array}\right)\left(\begin{array}{ccc}
1 & 0 & 0  \tag{4.40}\\
0 & h(2) & b(2)
\end{array}\right)\left(\begin{array}{cc}
I_{2} & 0 \\
0 & H_{3}
\end{array}\right) .
$$

From (4.34) and (4.36) with $k=1$ we have

$$
\begin{align*}
& U_{1}(1,1: N)=G_{1}^{U}\left(\begin{array}{lll}
h_{U}(1) & \tilde{b}(2) & \hat{b}(2)
\end{array}\right)\left(\begin{array}{cc}
I_{2} & 0 \\
0 & H_{3}
\end{array}\right)=  \tag{4.41}\\
& \left(G_{1}^{U} h_{U}(1) \quad G_{1}^{U} \tilde{b}(2) \quad G_{1}^{U} \hat{b}(2) H_{3}\right) .
\end{align*}
$$

By using (4.11) we find that

$$
U_{1}(2: 3,1: N)=\left(\begin{array}{ccc}
s_{2} & \eta_{2} & v_{2} b(2) H_{3}  \tag{4.42}\\
\rho_{2} & \beta_{2} & g(3) H_{3}
\end{array}\right)
$$

By combining (4.41) and (4.42) together we obtain (4.38) with $k=1$.
Let us now assume that for some $k$ with $2 \leq k \leq N-3$ the representation

$$
U_{k-1}(1: k+1, k-1: N)=\left(\begin{array}{ccc}
G_{k-1}^{U} h_{U}(k-1) & G_{k-1}^{U} \tilde{b}(k) & G_{k-1}^{U} \hat{b}(k) H_{k+1}  \tag{4.43}\\
s_{k} & \eta_{k} & v_{k} b(k) H_{k+1} \\
\rho_{k} & \beta_{k} & g(k+1) H_{k+1}
\end{array}\right)
$$

holds. By using (4.7) and (4.28), (4.29) it follows that

$$
\begin{gathered}
A_{k-1}(k: k+1, k-1)=U_{k-1}(k: k+1, k-1)-p_{k-1}(k: k+1) q_{k-1}(k-1)= \\
\binom{s_{k}}{\rho_{k}}-\binom{c_{k}}{p(k+1)} q^{(1)}(k-1)
\end{gathered}
$$

and, therefore, to get zero entry in the position $(k+1, k-1)$ in the matrix $A_{k}^{\prime}=\tilde{Q}_{k}^{*} A_{k-1}$ one should take $Q_{k}$ such that (4.13) holds. Next by using (4.13), (4.14) and (4.16), (4.17) we get

$$
U_{k}^{\prime}(1: k+1, k-1: N)=\left(\begin{array}{ccc}
G_{k-1}^{U} h_{U}(k-1) & G_{k-1}^{U} \tilde{b}(k) & G_{k-1}^{U} \hat{b}(k) H_{k+1}  \tag{4.44}\\
\sigma_{k-1}^{(1)} & \gamma_{k} & w_{k} H_{k+1} \\
c_{k+1} q^{(1)}(k-1) & f_{k+1} & v_{k+1} H_{k+1}
\end{array}\right) .
$$

From (4.28), (4.29), (4.7) and the fact that $A_{k}^{\prime}$ is upper Hessenberg we deduce that $U_{k}^{\prime}(k+2, k)=p(k+2) \theta_{k}$. Hence, by using (4.31), (2.12), (2.11) together
with (4.44) we obtain

$$
\begin{gathered}
U_{k}^{\prime}(1: k+2, k: N)= \\
\left(\begin{array}{ccc}
G_{k-1}^{U} \tilde{b}(k) & G_{k-1}^{U} \hat{b}(k) h(k+1) & G_{k-1}^{U} \hat{b}(k) b(k+1) H_{k+2} \\
\gamma_{k} & w_{k} h(k+1) & w_{k} b(k+1) H_{k+2} \\
f_{k+1} & v_{k+1} h(k+1) & v_{k+1} b(k+1) H_{k+2} \\
p(k+2) \theta_{k} & \sigma_{k+1} & g(k+2) H_{k+2}
\end{array}\right) .
\end{gathered}
$$

From the decomposition

$$
\begin{aligned}
& U_{k}^{\prime}(1: k, k: N)= \\
& \left(\begin{array}{cc}
G_{k-1}^{U} b(k) & G_{k-1}^{U} \hat{b}(k) \\
\gamma_{k} & w_{k}
\end{array}\right)\left(\begin{array}{ccc}
1 & 0 & 0 \\
0 & h(k+1) & b(k+1)
\end{array}\right)\left(\begin{array}{cc}
I_{2} & 0 \\
0 & H_{k+2}
\end{array}\right)
\end{aligned}
$$

by applying (4.34) and (4.36) one finds that

$$
\begin{equation*}
U_{k}(1: k, k: N)=G_{k}^{U}\left(h_{U}(k) \quad \tilde{b}(k+1) \quad \hat{b}(k+1) H_{k+2}\right) . \tag{4.45}
\end{equation*}
$$

From (4.15) it is also seen that

$$
U_{k}(k+1: k+2, k: N)=\left(\begin{array}{ccc}
s_{k+1} & \eta_{k+1} & v_{k+1} b(k+1) H_{k+2}  \tag{4.46}\\
\rho_{k+1} & \beta_{k+1} & g(k+2) H_{k+2}
\end{array}\right) .
$$

By combining (4.45) and (4.46) together we obtain (4.38).
Now (4.38) with $k=N-2$ gives

$$
\begin{gather*}
U_{N-2}(1: N, N-2: N)= \\
\left(\begin{array}{ccc}
G_{N-2}^{U} h_{U}(N-2) & G_{N-2}^{U} \tilde{b}(N-1) & G_{N-2}^{U} \hat{b}(N-1) h(N) \\
s_{N-1} & \eta_{N-1} & v_{N-1} b(N-1) h(N) \\
\rho_{N-1} & \beta_{N-1} & g(N) h(N)
\end{array}\right) . \tag{4.47}
\end{gather*}
$$

In the same way as above we obtain (4.18). By using (4.18), (4.19) and (4.21), (4.22) we deduce that

$$
\begin{align*}
& U_{N-1}^{\prime}(1: N, N-2: N)= \\
& \left(\begin{array}{ccc}
G_{N-2}^{U} h_{U}(N-2) & G_{N-2}^{U} \tilde{b}(N-1) & G_{N-2}^{U} \hat{b}(N-1) h(N) \\
\sigma_{N-2}^{(1)} & \gamma_{N-1} & w_{N-1} h(N) \\
p^{(1)}(N) q^{(1)}(N-2) & f_{N} & v_{N} h(N)
\end{array}\right) . \tag{4.48}
\end{align*}
$$

From (4.34) with $k=N-1$ it follows that

$$
U_{N-1}^{\prime}(1: N-1, N-1: N)=G_{N-1}^{U}\left(\begin{array}{cc}
1 & 0 \\
0 & h(N)
\end{array}\right)
$$

By using (4.20) and (4.37) we obtain

$$
U_{N-1}(1: N, N-1: N)=\left(\begin{array}{cc}
G_{N-1}^{U} h_{U}(N-1) & G_{N-1}^{U} b_{U}(N-1)  \tag{4.49}\\
s_{N} & \eta_{N}
\end{array}\right)
$$

In the view of (4.34) with $k=N$ and $h_{U}(N)=1$ this implies that

$$
\begin{equation*}
U_{N-1}(1: N, N)=G_{N}^{U} h_{U}(N) \tag{4.50}
\end{equation*}
$$

Thus, by using (4.44), (4.48) and (4.30) we get

$$
\sigma_{k-1}^{(1)}=U^{\prime}(k, k-1)=U^{(1)}(k, k-1), \quad k=2, \ldots, N-1
$$

and using (4.49) and (4.32) we have

$$
\sigma_{N-1}^{(1)}=s_{N}=U_{N-1}(N, N-1)=U^{(1)}(N, N-1)
$$

Hence it follows that $\sigma_{k}^{(1)}(k=1, \ldots, N-1)$ are the subdiagonal entries of the matrix $U^{(1)}$. Finally, from (4.38), (4.49), (4.50) and (4.32) we deduce that

$$
U^{(1)}(1: k, k)=G_{k}^{U} h_{U}(k), \quad k=1, \ldots, N .
$$

By virtue of Lemma 2.2 this relation implies that $g_{U}(i), h_{U}(i)(i=1, \ldots, N)$, and $b_{U}(k)(k=1, \ldots, N-1)$ are upper triangular generators of the matrix $U^{(1)}$. The orders of these generators equal $r_{k}^{\prime}=r_{k+1}+1, k=1, \ldots, N-$ $1, r_{N}^{\prime}=1$. By applying Theorem 3.1 we obtain upper triangular generators $g^{(1)}(i), h^{(1)}(i)(i=1, \ldots, N), b^{(1)}(k)(k=1, \ldots, N-1)$ of the matrix $U^{(1)}$ with orders defined in (4.27) and this concludes the proof.

The structured single-shift QR iteration applied to an input matrix $A=$ $A_{0} \in \mathcal{H}_{N}$ requires a linear number of arithmetic operations per step by using linear storage. Experimental comparisons with customary eigensolvers are shown in Sect. 6.

## 5. The Structured QR Iteration: The Double-Shift Case

The double-shift technique is employed to compute a pair of complex conjugate eigenvalues of a real upper Hessenberg matrix by using real arithmetic only. A double-shift step of the QR iteration (2.2) consists of the computation of a new iterant $A^{(1)}$ generated from $A=A^{(0)}$ with shift polynomial $q(z)=(z-\alpha)(z-\bar{\alpha})=z^{2}-s z+t, s, t \in \mathbb{R}$. The implicit version proceeds by finding the unitary matrix $Q$ of the form

$$
\begin{equation*}
Q=\tilde{Q}_{1} \tilde{Q}_{2} \cdots \tilde{Q}_{N-2} \tilde{Q}_{N-1}, \tag{5.1}
\end{equation*}
$$

where $\tilde{Q}_{i} \in \mathbb{C}^{N \times N}$ are unitary matrices satisfying

$$
\begin{equation*}
\tilde{Q}_{i}=I_{i-1} \oplus Q_{i} \oplus I_{N-i-2}, i=1, \ldots, N-2, \quad \tilde{Q}_{N-1}=I_{N-2} \oplus Q_{N-1} . \tag{5.2}
\end{equation*}
$$

These matrices are determined so that $\left(\tilde{Q}_{1}^{*} q(A)\right)(2: 3,1)=(00)^{T}$ and $A^{(1)}=$ $Q^{*} A Q$ is an upper Hessenberg matrix.

By using a standard bulge-chasing approach one computes the unitary matrices $Q_{i}(i=1, \ldots, N-1)$ and then the matrix $A^{(1)}$ as follows. At the first step we determine the $3 \times 3$ unitary matrix $Q_{1}$ from the condition

$$
Q_{1}^{*}(q(A)(1: 3,1))=\left(\begin{array}{ccc}
* & 0 & 0 \tag{5.3}
\end{array}\right)^{T} .
$$

Next we compute the matrix $A_{1}=\tilde{Q}_{1}^{*} A \tilde{Q}_{1}$ which is similar to the matrix $A$ and contains nonzero entries in the positions $(3,1)$ and $(4,1)$. We choose the matrix $Q_{2}$ in order to annihilate these entries, i.e. to obtain the matrix $A_{2}^{\prime}=\tilde{Q}_{2}^{*} A_{1}$ with zero entries below the first subdiagonal in the first column. Then we compute the matrix $A_{2}=A_{2}^{\prime} \tilde{Q}_{2}$. The matrix $A_{2}$ is similar to the matrix $A$ and contains nonzero entries in the positions $(4,2),(5,2)$. We choose the matrix $Q_{3}$ in order to annihilate these entries, i.e. to obtain the matrix $A_{3}^{\prime}=\tilde{Q}_{3}^{*} A_{2}$ with zero entries below the first subdiagonal in the second column. Then we compute the matrix $A_{3}=A_{3}^{\prime} \tilde{Q}_{3}$. The matrix $A_{3}$ is similar to the matrix $A$ and contains nonzero entries in the positions (5, 3), (6, 3). We continue this procedure for $k=4,5, \ldots, N-2$ and obtain the matrix $A_{N-2}$ with a nonzero entry in the $(N, N-2)$ position. To annihilate this entry we determine a Givens rotation matrix $Q_{N-1}$ and obtain $A_{N-1}^{\prime}=\tilde{Q}_{N-1}^{*} A_{N-2}$ and finally the upper Hessenberg matrix $A^{(1)}=A_{N-1}=A_{N-1}^{\prime} Q_{N-1}$. Thus we obtain the sequence (4.3) to determine the new iterant $A^{(1)}$ in the doubleshift case.

The next result reformulates the process in terms of generators by providing a structured QR iteration for the double-shift step applied to an input matrix $A \in \mathcal{H}_{N}$.

Theorem 5.1. Let $A=U-p q^{T}$ be a real matrix from the class $\mathcal{H}_{N}$ with vectors of perturbation $p=\operatorname{col}(p(i))_{i=1}^{N}, q=\operatorname{col}(q(i))_{i=1}^{N}$, upper triangular generators $g(i), h(i)(i=1, \ldots, N), b(k)(k=1, \ldots, N-1)$ of orders $r_{k}(k=1, \ldots, N)$ and subdiagonal entries $\sigma_{k}(k=1, \ldots, N-1)$ of the orthogonal matrix $U$, and let $s, t$ be real numbers. Then the unitary matrices $Q_{k}, k=1, \ldots, N-1$, the vectors of perturbation $p^{(1)}=\operatorname{col}\left(p^{(1)}(i)\right)_{i=1}^{N}, q^{(1)}=$ $\operatorname{col}\left(q^{(1)}(i)\right)_{i=1}^{N}$ of the upper Hessenberg matrix $A^{(1)}=Q^{*} A Q$, as well as subdiagonal entries $\sigma_{k}^{(1)}(k=1, \ldots, N-1)$ and the upper triangular generators $g^{(1)}(i), h^{(1)}(i)(i=1, \ldots, N), b^{(1)}(k)(k=1, \ldots, N-1)$ with orders not greater than two of the unitary matrix $U^{(1)}$ from (4.8) are determined by the following procedure.

1. Compute the unitary matrices $Q_{k}, k=1, \ldots, N-1$, the vectors of perturbation $p^{(1)}=\operatorname{col}\left(p^{(1)}(i)\right)_{i=1}^{N}, \quad q^{(1)}=\operatorname{col}\left(q^{(1)}(i)\right)_{i=1}^{N}$ of the upper Hessenberg matrix $A^{(1)}=Q^{*} A Q$ and the the subdiagonal entries $\sigma_{k}^{(1)}(k=1, \ldots, N-1)$ of the unitary matrix $U^{(1)}$, by performing these steps.
(a) Set

$$
\begin{gather*}
a_{11}=g(1) h(1)-p(1) q(1), \quad a_{12}=g(1) b(1) h(2)-p(1) q(2), \\
a_{22}=g(2) h(2)-p(2) q(2), \\
a_{21}=\sigma_{1}-p(2) q(1), \quad a_{32}=\sigma_{2}-p(3) q(2), \tag{5.4}
\end{gather*}
$$

compute

$$
v=\left(\begin{array}{lll}
a_{11}^{2}+a_{12} a_{21}-s a_{21}+t & a_{21}\left(a_{11}+a_{22}-s\right) & a_{32} a_{21}
\end{array}\right)^{T},
$$

and determine the $3 \times 3$ orthogonal matrix $Q_{1}$ from the condition

$$
Q_{1}^{*} v=\left(\begin{array}{ccc}
* & 0 & 0 \tag{5.5}
\end{array}\right)^{T} .
$$

Set

$$
\begin{equation*}
\theta_{2}=(q(1) \quad q(2)) . \tag{5.6}
\end{equation*}
$$

Compute

$$
\begin{align*}
&\left(\begin{array}{ll}
\gamma_{1} & w_{1} \\
f_{3} & v_{3}
\end{array}\right)= Q_{1}^{*}\left(\begin{array}{ccc}
g(1) h(1) & g(1) b(1) h(2) & g(1) b(1) b(2) \\
\sigma_{1} & g(2) h(2) & g(2) b(2) \\
p(3) q(1) & \sigma_{2} & g(3)
\end{array}\right),  \tag{5.7}\\
&\left(\begin{array}{cc}
s_{2} & \eta_{2} \\
\rho_{2} & \beta_{2}
\end{array}\right)=\left(\begin{array}{cc}
f_{3} & v_{3} h(3) \\
p(4) \theta_{2} & \sigma_{3}
\end{array}\right) Q_{1},  \tag{5.8}\\
&\binom{p^{(1)}(1)}{c_{3}}=Q_{1}^{*}\binom{c_{2}}{p(3)},  \tag{5.9}\\
& H_{1}=\left(\begin{array}{cc}
f_{3}-c_{3} \theta_{2} & v_{3} h(3)-c_{3} q(3) \\
0_{1 \times 2} & \sigma_{3}-p(4) q(3)
\end{array}\right) Q_{1},  \tag{5.10}\\
&\left(\begin{array}{lll}
q^{(1)}(1) & \theta_{3}
\end{array}\right)=\left(\begin{array}{ccc}
q(1) & q(2) & q(3)) Q_{1}
\end{array}\right. \tag{5.11}
\end{align*}
$$

with matrices $\gamma_{1}, w_{1}, f_{3}, v_{3}, s_{2}, \eta_{2}, \rho_{2}, \beta_{2}, c_{3}, \theta_{3}, H_{1}$ of sizes $1 \times 2,1 \times$ $r_{3}, 2 \times 2,2 \times r_{3}, 2 \times 1,2 \times 2,1 \times 1,1 \times 2,2 \times 1,1 \times 2,3 \times 3$ respectively.
(b) For $k=2, \ldots, N-3$ perform the following computation. Determine the $3 \times 3$ unitary matrix $Q_{k}$ and the number $\delta_{k-1}$ such that

$$
Q_{k}^{*} H_{k-1}(1: 3,1)=\left(\begin{array}{c}
\delta_{k-1}  \tag{5.12}\\
0 \\
0
\end{array}\right)
$$

Compute

$$
\begin{gather*}
\left(\begin{array}{cc}
\gamma_{k} & w_{k} \\
f_{k+2} & v_{k+2}
\end{array}\right)=Q_{k}^{*}\left(\begin{array}{cc}
\eta_{k} & v_{k+1} b(k+1) \\
\beta_{k} & g(k+2)
\end{array}\right),  \tag{5.13}\\
\left(\begin{array}{cc}
s_{k+1} & \eta_{k+1} \\
\rho_{k+1} & \beta_{k+1}
\end{array}\right)=\left(\begin{array}{cc}
f_{k+2} & v_{k+2} h(k+2) \\
p(k+3) \theta_{k+1} & \sigma_{k+2}
\end{array}\right) Q_{k} .  \tag{5.14}\\
\binom{p^{(1)}(k)}{c_{k+2}}=Q_{k}^{*}\binom{c_{k+1}}{p(k+2)},  \tag{5.15}\\
H_{k}=\left(\begin{array}{cc}
f_{k+2}-c_{k+2} \theta_{k+1} & v_{k+2} h(k+2)-c_{k+2} q(k+2) \\
0_{1 \times 2} & \sigma_{k+2}-p(k+3) q(k+2)
\end{array}\right) Q_{k} . \\
\left(\begin{array}{cc}
q^{(1)}(k) & \theta_{k+2}
\end{array}\right)=\left(\begin{array}{ll}
\theta_{k+1} & q(k+2)) Q_{k}, \\
\sigma_{k-1}^{(1)}=\delta_{k-1}+p^{(1)}(k) q^{(1)}(k-1)
\end{array}\right. \tag{5.16}
\end{gather*}
$$

with matrices $\gamma_{k}, w_{k}, f_{k+2}, v_{k+2}, s_{k+1}, \eta_{k+1}, \rho_{k+1}, \beta_{k+1}, c_{k+2}, \theta_{k+2}, H_{k}$ of sizes $1 \times 2,1 \times r_{k+2}, 2 \times 2,2 \times r_{k+2}, 2 \times 1,2 \times 2,1 \times 1,1 \times 2,2 \times$ $1,1 \times 2,3 \times 3$ respectively.
(c) Find the $3 \times 3$ unitary matrix $Q_{N-2}$ and the number $\delta_{N-2}$ such that

$$
Q_{N-2}^{*} H_{N-3}(1: 3,1)=\left(\begin{array}{c}
\delta_{N-3}  \tag{5.19}\\
0 \\
0
\end{array}\right)
$$

Compute

$$
\begin{align*}
& \left(\begin{array}{cc}
\gamma_{N-2} & w_{N-2} \\
f_{N} & v_{N}
\end{array}\right)=Q_{N-2}^{*}\left(\begin{array}{cc}
\eta_{N-2} & v_{N-1} b(N-1) \\
\beta_{N-2} & g(N)
\end{array}\right),  \tag{5.20}\\
& \left(\begin{array}{cc}
s_{N-1} & \eta_{N-1}
\end{array}\right)=\left(\begin{array}{ll}
f_{N} & v_{N} h(N)
\end{array}\right) Q_{N-2},  \tag{5.21}\\
& \binom{p^{(1)}(N-2)}{c_{N}}=Q_{N-2}^{*}\binom{c_{N-1}}{p(N)},  \tag{5.22}\\
& H_{N-2}=\left(f_{N}-c_{N} \theta_{N-1} \quad v_{N} h(N)-c_{N} q(N)\right) Q_{N-2} \text {, }  \tag{5.23}\\
& \left(\begin{array}{ll}
q^{(1)}(N-2) & \theta_{N}
\end{array}\right)=\left(\begin{array}{ll}
\theta_{N-1} & q(N)
\end{array}\right) Q_{N-2},  \tag{5.24}\\
& \sigma_{N-3}^{(1)}=\delta_{N-3}+p^{(1)}(N-2) q^{(1)}(N-3) . \tag{5.25}
\end{align*}
$$

with matrices $\gamma_{N-2}, w_{N-2}, f_{N}, v_{N}, s_{N-1}, \eta_{N-1}, \rho_{N-1}, \beta_{N-1}, c_{N}, \theta_{N}$, and $H_{N-2}$ of sizes $1 \times 2,1 \times r_{N}, 2 \times 2,2 \times r_{N}, 2 \times 1,2 \times 2,1 \times 1,1 \times$ $2,2 \times 1,1 \times 2,2 \times 2$ respectively.
(d) Compute the Givens rotation matrix $Q_{N-1}$ and the number $\delta_{N-2}$ such that

$$
\begin{equation*}
Q_{N-1}^{*} H_{N-2}(1: 2,1)=\binom{\delta_{N-2}}{0} \tag{5.26}
\end{equation*}
$$

Compute

$$
\begin{gather*}
\binom{\gamma_{N-1}}{f_{N+1}}=Q_{N-1}^{*} \eta_{N-1},  \tag{5.27}\\
\left(s_{N} \eta_{N}\right)=f_{N+1} Q_{N-1},  \tag{5.28}\\
\binom{p^{(1)}(N-1)}{p^{(1)}(N)}=Q_{N-1}^{*} c_{N},\left(q^{(1)}(N-1) q^{(1)}(N)\right)=\theta_{N} Q_{N-1},  \tag{5.30}\\
\sigma_{N-2}^{(1)}=  \tag{5.29}\\
\delta_{N-2}+p^{(1)}(N-1) q^{(1)}(N-2)
\end{gather*}
$$

with two-dimensional rows $\gamma_{N-1}, f_{N+1}$ and numbers $s_{N}, \eta_{N}$. Set $\sigma_{N-1}^{(1)}=s_{N}$.
2. Determine the matrices $h_{Q}(k), b_{Q}(k), d_{Q}(k), g_{Q}(k)$ of sizes $2 \times 1,2 \times$ $2,1 \times 1,1 \times 2$ from the partitions

$$
Q_{k}=\left(\begin{array}{cc}
h_{Q}(k) & b_{Q}(k)  \tag{5.31}\\
d_{Q}(k) & g_{Q}(k)
\end{array}\right), \quad k=1, \ldots, N-2
$$

and the two-dimensional columns $h_{Q}(N-1), b_{Q}(N-1)$ from the partition

$$
\begin{equation*}
Q_{N-1}=\left(h_{Q}(N-1) \quad b_{Q}(N-1)\right) . \tag{5.32}
\end{equation*}
$$

Set

$$
\begin{gather*}
g_{U}(k)=\left(\begin{array}{ll}
\gamma_{k} & w_{k}
\end{array}\right), k=1, \ldots, N-2,  \tag{5.33}\\
g_{U}(N-1)=\gamma_{N-1}, \quad g_{U}(N)=\eta_{N}, \\
h_{U}(k)=\binom{h_{Q}(k)}{h(k+2) d_{Q}(k)}, k=1, \ldots, N-2,  \tag{5.34}\\
h_{U}(N-1)=h_{Q}(N-1), \\
h_{U}(N)=1, \\
b_{U}(k)=\left(\begin{array}{cc}
b_{Q}(k) & 0 \\
h(k+2) g_{Q}(k) & b(k+2)
\end{array}\right), k=1, \ldots, N-3,  \tag{5.35}\\
b_{U}(N-2)=\binom{b_{Q}(N-2)}{h(N) g_{Q}(N-2)}, \quad b_{U}(N-1)=b_{Q}(N-1) .
\end{gather*}
$$

3. By using the algorithm from Theorem 3.1 compute upper triangular generators $g^{(1)}(i), h^{(1)}(i)(i=1, \ldots, N), b^{(1)}(k)(k=1, \ldots, N-1)$ of orders

$$
t_{k}=2, k=1, \ldots, N-1, \quad t_{N}=1
$$

of the matrix $U^{(1)}$.
Remark 5.2. The "bulge vector" $H_{k-1}(1: 3,1)$, which is used in (5.12) to determine $Q_{k}$, can also, in principle, be computed as

$$
H_{k-1}(1: 3,1)=\binom{s_{k}-c_{k+1} q^{(1)}(k-1)}{\rho_{k}-p(k+2) q^{(1)}(k-1)}
$$

thus making the computation of $H_{k}$ in (5.16) unnecessary. However, we prefer to compute the bulge vector as in (5.16) for reasons of numerical stability.

Proof. From the formulas (5.1), (5.2) it follows that the vectors $p_{k}, q_{k}$ from (4.5), (4.6) have the form

$$
\begin{equation*}
p_{k}=\left(p^{(1)}(1), \ldots, p^{(1)}(k), c_{k+2}, p(k+3), \ldots, p(N)\right)^{T}, \quad k=1, \ldots, N-2, \tag{5.36}
\end{equation*}
$$

$$
\begin{equation*}
q_{k}=\left(q^{(1)}(1), \ldots, q^{(1)}(k), \theta_{k+2}, q(k+3), \ldots, q(N)\right)^{T}, \quad k=1, \ldots, N-2, \tag{5.37}
\end{equation*}
$$

and moreover the formulas (5.9), (5.11), (5.15), (5.17), (5.22), (5.24) and (5.29) yield the coordinates of the vectors of perturbation $p^{(1)}=Q^{*} p, q^{(1)}=$ $Q^{T} q$. Furthermore from (4.4) one deduces the relations (4.30), (4.32) together with the equalities

$$
\begin{equation*}
U_{k}^{\prime}(k+3: N, k+2: N)=U(k+3: N, k+2: N), k=1, \ldots, N-3 . \tag{5.38}
\end{equation*}
$$

By using the matrices $g_{U}(k), b_{U}(k)$ define the matrices $G_{k}^{U}$ via the recursive relations (4.33). From (5.33), (5.35) we have

$$
\begin{gather*}
G_{1}^{U}=\left(\begin{array}{ll}
\gamma_{1} & w_{1}
\end{array}\right), \quad G_{k}^{U}=\left(\begin{array}{cc}
G_{k-1}^{U} \tilde{b}(k) & G_{k-1}^{U} \hat{b}(k) \\
\gamma_{k} & w_{k}
\end{array}\right), k=2, \ldots, N-2, \\
G_{N-1}^{U}=\binom{G_{N-2}^{U} b_{U}(N-2)}{\gamma_{N-1}}, \quad G_{N}^{U}=\binom{G_{N-1}^{U} b_{U}(N-1)}{\eta_{N}} \tag{5.39}
\end{gather*}
$$

with

$$
\begin{equation*}
\tilde{b}(k)=\binom{b_{Q}(k-1)}{h(k+1) g_{Q}(k-1)}, \hat{b}(k)=\binom{0_{1 \times r_{k+2}}}{b(k+1)}, k=2, \ldots, N-2 . \tag{5.40}
\end{equation*}
$$

Notice that from (5.31) one can rewrite the formulas (5.34), (5.35) in the form

$$
\left.\begin{array}{c}
\left(\begin{array}{cc}
h_{U}(k) \tilde{b}(k+1) & \hat{b}(k+1)
\end{array}\right)=\left(\begin{array}{ccc}
I_{2} & 0 & 0 \\
0 & h(k+2) & b(k+2)
\end{array}\right)\left(\begin{array}{cc}
Q_{k} & 0 \\
0 & I_{r_{k+3}}
\end{array}\right), \\
k=1, \ldots, N-3, \\
\left(h_{U}(N-2)\right.
\end{array} b_{U}(N-2)\right)=\left(\begin{array}{cc}
I_{2} & 0  \tag{5.41}\\
0 & h(N)
\end{array}\right) Q_{N-2} .
$$

We prove by induction that the relations

$$
\begin{equation*}
A_{k}(k+1: k+3, k: k+2)=H_{k}, \quad k=1, \ldots, N-3 \tag{5.43}
\end{equation*}
$$

with the matrices $H_{k}(k=1, \ldots, N-3)$ defined in (5.10), (5.16) hold, the $3 \times 3$ unitary matrices $Q_{k}, k=1, \ldots, N-3$ are determined via (5.5), (5.12)
and, moreover, that the relations

$$
\begin{gather*}
U_{k}(1: k+3, k: N)= \\
\left(\begin{array}{ccc}
G_{k}^{U} h_{U}(k) & G_{k}^{U} \tilde{b}(k+1) & G_{k}^{U} \hat{b}(k+1) H_{k+3} \\
s_{k+1} & \eta_{k+1} & v_{k+2} b(k+2) H_{k+3} \\
\rho_{k+1} & \beta_{k+1} & g(k+3) H_{k+3}
\end{array}\right), \quad k=1, \ldots, N-3 \tag{5.44}
\end{gather*}
$$

are fulfilled.
By using (2.6) and (2.9) we obtain the formulas (5.4). Hence to satisfy the condition (5.3) one should take the $3 \times 3$ unitary matrix $Q_{1}$ such that the condition (5.5) holds. From (2.6), (2.12) and (2.11) we find that $U(1$ : $4,1: N)$ can be specified as follows:

$$
\left(\begin{array}{cccc}
g(1) h(1) & g(1) b(1) h(2) & g(1) b(1) b(2) h(3) & g(1) b(1) b(2) b(3) H_{4} \\
\sigma_{1} & g(2) h(2) & g(2) b(2) h(3) & g(2) b(2) b(3) H_{4} \\
p(3) q(1) & \sigma_{2} & g(3) h(3) & g(3) b(3) H_{4} \\
p(4) q(1) & p(4) q(2) & \sigma_{3} & g(4) H_{4}
\end{array}\right) .
$$

From (5.7) and (5.6) we obtain

$$
U_{1}^{\prime}(1: 4,1: N)=\left(\begin{array}{ccc}
\gamma_{1} & w_{1} h(3) & w_{1} b(3) H_{4}  \tag{5.45}\\
f_{3} & v_{3} h(3) & v_{3} b(3) H_{4} \\
p(4) \theta_{2} & \sigma_{3} & g(4) H_{4}
\end{array}\right) .
$$

By using (4.3) and (4.7) we find that

$$
A_{1}(2: 4,1: 3)=A_{1}^{\prime}(2: 4,1: 3) Q_{1}=\left[U_{1}^{\prime}(2: 4,1: 3)-p_{1}(2: 4) q(1: 3)\right] Q_{1} .
$$

From (5.45), (5.36) and (5.6) this implies that

$$
A_{1}(2: 4,1: 3)=\left[\left(\begin{array}{cc}
f_{3} & v_{3} h(3) \\
p(4) \theta_{2} & \sigma_{3}
\end{array}\right)-\binom{c_{3}}{p(4)}\left(\begin{array}{ll}
\theta_{2} & q(3))
\end{array}\right)\right] Q_{1}
$$

which gives (5.43) with $k=1$.
The first row of the matrix $U_{1}^{\prime}$ can be expressed in the form

$$
U_{1}^{\prime}(1,1: N)=\left(\begin{array}{cc}
\gamma_{1} & w_{1}
\end{array}\right)\left(\begin{array}{ccc}
I_{2} & 0 & 0  \tag{5.46}\\
0 & h(3) & b(3)
\end{array}\right)\left(\begin{array}{cc}
I_{3} & 0 \\
0 & H_{4}
\end{array}\right) .
$$

Using (5.46) and (5.41) with $k=1$ yields

$$
\begin{align*}
& U_{1}(1,1: N)=G_{1}^{U}\left(\begin{array}{lll}
h_{U}(1) & \tilde{b}(2) & \hat{b}(2)
\end{array}\right)\left(\begin{array}{cc}
I_{2} & 0 \\
0 & H_{4}
\end{array}\right)=  \tag{5.47}\\
& \left(G_{1}^{U} h_{U}(1) \quad G_{1}^{U} \tilde{b}(2) \quad G_{1}^{U} \hat{b}(2) H_{4}\right) .
\end{align*}
$$

From (5.8) we deduce that

$$
U_{1}(2: 4,1: N)=\left(\begin{array}{ccc}
s_{2} & \eta_{2} & v_{3} b(3) H_{4}  \tag{5.48}\\
\rho_{2} & \beta_{2} & g(4) H_{4}
\end{array}\right) .
$$

By combining (5.47) and (5.48) together we obtain (5.44) with $k=1$.
Let us now assume that for some $k$ with $2 \leq k \leq N-4$ the relations

$$
\begin{equation*}
A_{k-1}(k: k+2, k-1: k+1)=H_{k-1} \tag{5.49}
\end{equation*}
$$

and
$U_{k-1}(1: k+1, k-1: N)=\left(\begin{array}{ccc}G_{k-1}^{U} h_{U}(k-1) & G_{k-1}^{U} \tilde{b}(k) & G_{k-1}^{U} \hat{b}(k) H_{k+2} \\ s_{k} & \eta_{k} & v_{k+1} b(k+1) H_{k+2} \\ \rho_{k} & \beta_{k} & g(k+2) H_{k+2}\end{array}\right)$
hold. Then from (5.49) it follows that in order to get zero entries in the positions $(k+1, k-1),(k+2, k-1)$ in the matrix $A_{k}^{\prime}=\tilde{Q}_{k}^{*} A_{k-1}$ one should take $Q_{k}$ such that (5.12) holds. By using the equalities (5.49), (5.50), (4.7), (5.36) and (5.37) there follows that

$$
\begin{gathered}
\binom{s_{k}}{\rho_{k}}=A_{k-1}(k: k+2, k-1)+p_{k-1}(k: k+2) q_{k-1}(k-1)= \\
H_{k-1}(:, 1)+\binom{c_{k+1}}{p(k+2)} q^{(1)}(k-1) .
\end{gathered}
$$

Hence from (5.12), (5.15) and (5.18) we obtain

$$
\begin{align*}
& Q_{k-1}^{*}\binom{s_{k}}{\rho_{k}}=\left(\begin{array}{c}
\delta_{k-1} \\
0 \\
0
\end{array}\right)+\binom{p^{(1)}(k+1)}{c_{k+2}} q^{(1)}(k-1)=  \tag{5.51}\\
& \binom{\sigma_{k-1}^{(1)}}{c_{k+2} q^{(1)}(k-1)} .
\end{align*}
$$

Thus by virtue of (5.50), (5.51) and (5.14) we find that

$$
U_{k}^{\prime}(1: k+2, k-1: N)=\left(\begin{array}{ccc}
G_{k-1}^{U} h_{U}(k-1) & G_{k-1}^{U} \tilde{b}(k) & G_{k-1}^{U} \hat{b}(k) H_{k+2}  \tag{5.52}\\
\sigma_{k-1}^{(1)} & \gamma_{k} & w_{k} H_{k+2} \\
c_{k+2} q^{(1)}(k-1) & f_{k+2} & v_{k+2} H_{k+2}
\end{array}\right) .
$$

By using (5.36), (5.37), (4.7) and the fact that $A_{k}^{\prime}$ has all zero entries below the first subdiagonal (except that one in the position $(k+2, k)$ ) we deduce that $U_{k}^{\prime}(k+3, k)=p(k+3) \theta_{k+1}$. Hence by using (5.38), (2.12), (2.11) together with (5.52) we get

$$
\begin{gather*}
U_{k}^{\prime}(1: k+3, k: N)= \\
\left(\begin{array}{ccc}
G_{k-1}^{U} \tilde{b}(k) & G_{k-1}^{U} \hat{b}(k) h(k+2) & G_{k-1}^{U} \hat{b}(k) b(k+2) H_{k+3} \\
\gamma_{k} & w_{k} h(k+2) & w_{k} b(k+2) H_{k+3} \\
f_{k+2} & v_{k+2} h(k+2) & v_{k+2} b(k+2) H_{k+3} \\
p(k+3) \theta_{k+1} & \sigma_{k+2} & g(k+3) H_{k+3}
\end{array}\right) . \tag{5.53}
\end{gather*}
$$

By using (4.3) and (4.7) we find that

$$
\begin{gathered}
A_{k}(k+1: k+3, k: k+2)=A_{k}^{\prime}(k+1: k+3, k: k+2) Q_{k}= \\
{\left[U_{k}^{\prime}(k+1: k+3, k: k+2)-p_{k}(k+1: k+3) q_{k-1}(k: k+2)\right] Q_{k}}
\end{gathered}
$$

In the view of (5.53), (5.36) and (5.37) this gives

$$
\begin{aligned}
& A_{k}(k+1: k+3, k: k+2)= \\
& {\left[\left(\begin{array}{cc}
f_{k+2} & v_{k+2} h(k+2) \\
p(k+3) \theta_{k+1} & \sigma_{k+2}
\end{array}\right)-\binom{c_{k+2}}{p(k+3)}\left(\begin{array}{ll}
\theta_{k+1} & q(k+2))
\end{array}\right] Q_{k}\right.}
\end{aligned}
$$

which implies (5.43).
Now let us consider the representation of $U_{k}^{\prime}(1: k, k: N)$ as

$$
\left(\begin{array}{cc}
G_{k-1}^{U} \tilde{b}(k) & G_{k-1}^{U} \hat{b}(k) \\
\gamma_{k} & w_{k}
\end{array}\right)\left(\begin{array}{ccc}
I_{2} & 0 & 0 \\
0 & h(k+2) & b(k+2)
\end{array}\right)\left(\begin{array}{cc}
I_{3} & 0 \\
0 & H_{k+3}
\end{array}\right) .
$$

By applying (5.39) and (5.41) we obtain

$$
\begin{equation*}
U_{k}(1: k, k: N)=G_{k}^{U}\left(h_{U}(k) \quad \tilde{b}(k+1) \quad \hat{b}(k+1) H_{k+3}\right) . \tag{5.54}
\end{equation*}
$$

By using (5.14) we get

$$
U_{k}(k+1: k+3, k: N)=\left(\begin{array}{ccc}
s_{k+1} & \eta_{k+1} & v_{k+2} b(k+2) H_{k+3}  \tag{5.55}\\
\rho_{k+1} & \beta_{k+1} & g(k+3) H_{k+3}
\end{array}\right) .
$$

Combining (5.54) and (5.55) together gives (5.44).

From (5.44) with $k=N-3$ we deduce that

$$
\begin{gather*}
U_{N-3}(1: N, N-3: N)= \\
\left(\begin{array}{ccc}
G_{N-3}^{U} h_{U}(N-3) & G_{N-3}^{U} \tilde{b}(N-2) & G_{N-3}^{U} \hat{b}(N-2) h(N) \\
s_{N-2} & \eta_{N-2} & v_{N-1} b(N-1) h(N) \\
\rho_{N-2} & \beta_{N-2} & g(N) h(N)
\end{array}\right) \tag{5.56}
\end{gather*}
$$

In the same way as above we obtain (5.19) and

$$
\begin{align*}
& U_{N-2}^{\prime}(1: N, N-3: N)= \\
& \left(\begin{array}{ccc}
G_{N-3}^{U} h_{U}(N-3) & G_{N-3}^{U} \tilde{b}(N-2) & G_{N-3}^{U} \hat{b}(N-2) h(N) \\
\sigma_{N-3}^{(1)} & \gamma_{N-2} & w_{N-2} h(N) \\
c_{N} q^{(1)}(N-2) & f_{N} & v_{N} h(N)
\end{array}\right) \tag{5.57}
\end{align*}
$$

By using (4.3) and (4.7) we find that

$$
\begin{gathered}
A_{N-2}(N-1: N, N-2: N)=A_{N-2}^{\prime}(N-1: N, N-2: N) Q_{N-2}= \\
{\left[U_{N-2}^{\prime}(N-1: N, N-2: N)-p_{N-2}(N-1: N) q_{N-3}(N-2: N)\right] Q_{N-2}}
\end{gathered}
$$

From this relation in the view of (5.57), (5.36) and (5.37) we obtain

$$
\begin{aligned}
& A_{N-2}(N-1: N, N-2: N)= \\
& {\left[\left(\begin{array}{ll}
f_{N} & v_{N} h(N)
\end{array}\right)-c_{N}\left(\begin{array}{ll}
\theta_{N-1} & q(N)
\end{array}\right)\right] Q_{N-2}}
\end{aligned}
$$

which implies

$$
\begin{equation*}
A_{N-2}(N-1: N, N-2: N)=H_{N-2} \tag{5.58}
\end{equation*}
$$

with the matrix $H_{N-2}$ defined in (5.23). Next from (5.57) and (5.39) with $k=N-2$ we have

$$
U_{N-2}^{\prime}(1: N-2, N-2: N)=G_{N-2}^{U}\left(\begin{array}{cc}
I_{2} & 0 \\
0 & h(N)
\end{array}\right)
$$

By using (5.21) and (5.42) we get

$$
U_{N-2}(1: N-2, N-2: N)=\left(\begin{array}{cc}
G_{N-2}^{U} h_{U}(N-2) & G_{N-2}^{U} b_{U}(N-2)  \tag{5.59}\\
s_{N-1} & \eta_{N-1}
\end{array}\right)
$$

From (5.58) it follows that in order to get zero entry in the position $(N, N-2)$ in the matrix $A_{N-1}^{\prime}=\tilde{Q}_{k}^{*} A_{N-2}$ one should take $Q_{N-1}$ such that
(5.26) holds. By using the equalities (5.58), (5.59), (4.7) and (5.36), (5.37) we find that

$$
\begin{aligned}
& s_{N-1}=A_{N-2}(N-1: N, N-2)+p_{N-2}(N-1: N) q_{N-2}(N-2)= \\
& H_{N-2}(:, 1)+c_{N} q^{(1)}(N-2)
\end{aligned}
$$

Hence from (5.26), (5.29) and (5.30) we obtain

$$
\begin{align*}
& Q_{N-1}^{*} s_{N-1}=\binom{\delta_{N-1}}{0}+\binom{p^{(1)}(N-1)}{p^{(1)}(N)} q^{(1)}(N-2)= \\
& \binom{\sigma_{N-2}^{(1)}}{p^{(1)}(N) q^{(1)}(N-2)} . \tag{5.60}
\end{align*}
$$

Thus by using (5.59), (5.60) and (5.27) we get

$$
U_{N-1}^{\prime}(1: N, N-2: N)=\left(\begin{array}{cc}
G_{N-2}^{U} h_{U}(N-2) & G_{N-2}^{U} b_{U}(N-2)  \tag{5.61}\\
\sigma_{N-2}^{(1)} & \gamma_{N-1} \\
p^{(1)}(N) q^{(1)}(N-2) & f_{N+1}
\end{array}\right)
$$

From (5.39) with $k=N-1$ we have

$$
U_{N-1}^{\prime}(1: N, N-1: N)=\binom{G_{N-1}^{U} Q_{N-1}}{f_{N+1} Q_{N-1}} \cdot\left(\begin{array}{cc}
I_{2} & 0 \\
0 & h(N)
\end{array}\right)
$$

Hence, (5.28), (5.32) and (5.34), (5.35) with $k=N-1$ imply

$$
U_{N-1}(1: N, N-1: N)=\left(\begin{array}{cc}
G_{N-1}^{U} h_{U}(N-1) & G_{N-1}^{U} b_{U}(N-1)  \tag{5.62}\\
s_{N} & \eta_{N}
\end{array}\right)
$$

In the view of (5.39) with $k=N$ and $h_{U}(N)=1$ this relation gives

$$
\begin{equation*}
U_{N-1}(1: N, N)=G_{N}^{U} h_{U}(N) \tag{5.63}
\end{equation*}
$$

Thus, by virtue of (5.52), (5.57), (5.61) and (4.30) we get

$$
\sigma_{k-1}^{(1)}=U^{\prime}(k, k-1)=U^{(1)}(k, k-1), \quad k=2, \ldots, N-1
$$

and from (5.62) and (4.32) this yields

$$
\sigma_{N-1}^{(1)}=s_{N}=U_{N-1}(N, N-1)=U^{(1)}(N, N-1)
$$

Hence it follows that $\sigma_{k}^{(1)}(k=1, \ldots, N-1)$ are the subdiagonal entries of the matrix $U^{(1)}$.

Furthermore, by using (5.44), (5.59), (5.63) and (4.32) we have

$$
U^{(1)}(1: k, k)=G_{k}^{U} h_{U}(k), \quad k=1, \ldots, N .
$$

From Lemma 2.2 this means that $g_{U}(i), h_{U}(i)(i=1, \ldots, N), b_{U}(k)(k=$ $1, \ldots, N-1$ ) are upper triangular generators of the matrix $U^{(1)}$. The orders of these generators equal $r_{k}^{\prime}=r_{k+2}+1, k=1, \ldots, N-2, r_{N-1}^{\prime}=$ $2, r_{N}^{\prime}=1$. By applying Theorem 3.1 we obtain upper triangular generators $g^{(1)}(i), h^{(1)}(i)(i=1, \ldots, N), b^{(1)}(k)(k=1, \ldots, N-1)$ of the matrix $U^{(1)}$ with orders defined in (4.27).

Analogously with the single-shift case we may conclude that the structured double-shift QR iteration applied to an input matrix $A=A_{0} \in \mathcal{H}_{N}$ requires a linear number of arithmetic operations per step by using linear storage. Experimental comparisons with customary eigensolvers are also shown in Sect. 6.

## 6. Numerical tests

In order to test the performance of the proposed structured QR iterations, we implemented the single-shift strategy in Matlab and in Fortran 90/95, and the double-shift strategy in Matlab. The Fortran implementation has been used for timing comparisons. The codes can be downloaded from the URL
http://www.unilim.fr/pages_perso/paola.boito/software.html
A crucial point in the implementation of the QR method is deflation. Deflation occurs when the current iterate matrix $A$ is reducible, that is, when a subdiagonal entry happens to be negligible. In this case the eigenvalue problem splits into two subproblems of smaller size. If the negligible subdiagonal entry is in last or last-but-one position, then one eigenvalue or a pair of complex conjugate eigenvalues, respectively, has converged. In the present implementations:

- Deflation is performed according to the classical Wilkinson criterion, i.e., a subdiagonal entry $A(k+1, k)$ is considered small enough for deflation if $|A(k+1, k)|<\epsilon(|A(k, k)|+|A(k+1, k+1)|)$, where $\epsilon$ is the machine epsilon;
- Deflation is also performed when the product of two consecutive subdiagonal entries is small enough to ensure that the current iterate is numerically reducible; see e.g. [9], [6] and [1] for details.

The accuracy and stability of our algorithms has been measured in the numerical experiments by computing backward and forward errors. Let $p(z)=$ $\sum_{j=0}^{N} c_{j} z^{j}=c_{n} \prod_{j=1}^{N}\left(z-\alpha_{j}\right)$ be a test polynomial; denote as $\left\{\tilde{\alpha}_{j}\right\}_{j=1, \ldots, N}$ the roots of $p(z)$ computed by the method that is being analyzed, and as $\left\{\tilde{c}_{j}\right\}_{j=0, \ldots, N}$ the coefficients of a polynomial having $\left\{\tilde{\alpha}_{j}\right\}_{j=1, \ldots, N}$ as "exact" roots. Here the coefficients $\left\{\tilde{c}_{j}\right\}_{j=0, \ldots, N}$ are computed in MatLaB by using the high precision arithmetic environment.

We use the following definitions for errors:

- Absolute forward error: $\operatorname{MaxEigAbs}=\max _{j=1, \ldots, N} \min _{k=1, \ldots, N}\left|\alpha_{j}-\tilde{\alpha}_{k}\right|$.
- Relative forward error: $\mathrm{MaxEigRel}=\max _{\alpha_{j} \neq 0, j=1, \ldots, N} \min _{k=1, \ldots, N} \frac{\left|\alpha_{j}-\tilde{\alpha}_{k}\right|}{\left|\alpha_{j}\right|}$.
- Absolute backward error: MaxCoeffAbs $=\max _{j=0, \ldots, N}\left|c_{j}-\tilde{c}_{j}\right|$.
- Relative backward error: MaxCoeffRel $=\max _{c_{j} \neq 0, j=0, \ldots, N} \frac{\mid{\left|c_{j}-\tilde{c}_{j}\right|}_{\left|c_{j}\right|} .}{}$

For practical purposes, when $p(z)$ is defined by its coefficient we take as "exact" roots $\left\{\alpha_{j}\right\}_{j=1, \ldots, n}$ the roots computed by LAPACK routines ZGEEV (for complex coefficients) or DGEEV (for real coefficients), or by the Matlab command roots. On the other hand, if $p(z)$ is defined by its roots, then we compute its "exact" coefficients $\left\{c_{j}\right\}_{j=0, \ldots, N}$ by using high precision arithmetic.

In Examples 1 and 2, we consider polynomials of large degree (random and cyclotomic), useful to check the growth of running time and the stability of the algorithm. The Fortran implementation of the single shift strategy is employed here, with the exception of Example 1bis. The machine we used to run the Fortran code is a laptop with an AMD Turion processor and 2 GB RAM, equipped with the f95 compiler under Linux Ubuntu. We have observed, however, that the same code may give slightly different results on different machines. We have also compared the performance of the algorithm described in the present paper to the fast QR algorithm presented in [1] referred to as the "Old" algorithm. For the sake of comparison the time time_L reported by the LAPACK routine is also indicated.

| N | time (old) | error (old) | time (new) | error (new) | time_L |
| :--- | :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |  |
| 50 | 0.0230 | $8.50 e-15$ | 0.0196 | $6.35 e-15$ | 0.00950 |
| 100 | 0.0685 | $3.23 e-14$ | 0.0584 | $1.25 e-14$ | 0.0446 |
| 150 | 0.136 | $7.00 e-14$ | 0.109 | $1.63 e-14$ | 0.134 |
| 200 | 0.278 | $1.03 e-13$ | 0.223 | $2.94 e-14$ | 0.320 |
| 300 | 0.605 | $2.77 e-13$ | 0.505 | $3.95 e-14$ | 1.10 |
| 400 | 1.00 | $4.34 e-13$ | 0.754 | $4.69 e-14$ | 2.67 |
| 500 | 1.59 | $6.31 e-13$ | 1.17 | $8.66 e-14$ | 5.17 |
| 600 | 2.48 | $8.82 e-13$ | 1.92 | $1.02 e-14$ | 8.64 |
| 700 | 3.64 | $1.54 e-12$ | 2.64 | $1.07 e-13$ | 14.65 |
| 800 | 4.45 | $2.11 e-12$ | 3.01 | $1.21 e-13$ | 23.13 |
| 900 | 5.67 | $1.95 e-12$ | 4.30 | $1.36 e-13$ | 31.15 |
| 1000 | 6.99 | $2.27 e-12$ | 4.96 | $1.84 e-13$ | 40.44 |
|  |  |  |  |  |  |
| 3000 | 63.88 | $1.55 e-11$ | 50.00 | $6.67 e-13$ | 1250.32 |
| 5000 | 197.81 | $4.74 e-11$ | 154.66 | $1.81 e-12$ | 7595.66 |

Table 1: Average results for complex polynomials with random coefficients. Times are measured in seconds. "Old" refers to the algorithm in [1], "new" to the algorithm described in the present paper.

Example 1. In this example we consider polynomials with complex coefficients whose real and imaginary parts are randomly chosen in the range $[-1,1]$. Table 1 shows, for several values of the degree, the average errors and timings over 10 polynomials. The cases $N=3000$ and $N=5000$ are exceptions in that a single polynomial has been used. Further, we have computed a linear fit on logarithmic timings for our algorithm, for random polynomials of degrees $100,200,300, \ldots, 2000$. The resulting slope is 2.01 , which supports the theoretical result of $\mathcal{O}\left(N^{2}\right)$ overall complexity for approximating all the roots of a polynomial of degree $N$.

Example 1bis. We also test the Matlab implementation of the double shift strategy for random polynomials (this time with real coefficients): see Table 2. For each value of the degree, results are computed as an average over 10 polynomials.

Example 2. Given a degree $N$, consider the complex polynomial $p_{N}(z)=$

| $N$ | MaxEigAbs | N_it |
| :---: | :---: | :---: |
|  |  |  |
| 100 | $1.03 e-14$ | 1.69 |
| 200 | $2.15 e-14$ | 1.58 |
| 300 | $4.35 e-14$ | 1.58 |
| 400 | $4.63 e-14$ | 1.50 |
| 500 | $9.43 e-14$ | 1.49 |
| 600 | $7.21 e-14$ | 1.53 |
| 700 | $1.05 e-13$ | 1.46 |

Table 2: Average results for the Matlab double shift implementation applied to real polynomials with random coefficients; N_it denotes the average number of iterations per eigenvalue.
$z^{N}-i$, where $i$ is the imaginary unit. Table 3 shows the errors and timings for several values of the degree $N$.

## Example 3.

This example presents ill-conditioned polynomials of small degree, which provide a test for backward stability and for the accuracy of computed results. We use here the Matlab implementation, in the double shift version except for the last polynomial, which has complex coefficients.

Following [8], we also explore the effect of balancing. Balancing amounts to replacing the original companion matrix $A$ with $D A D^{-1}$, where $D$ is a diagonal matrix. Ideally, the variation in magnitude of the elements of the new matrix should be smaller than for $A$, thus improving the performance of a numerical rootfinder. For a structured approach, the matrix $D$ needs to be chosen of the form $D=\operatorname{diag}\left(\beta, \beta^{2}, \beta^{N}\right)$ for a suitable parameter $\beta$ which amounts to a scaling of the polynomial, i.e., to compute the roots of the scaled polynomial $\hat{p}(z)=p(\beta z)$. We therefore obtain

$$
D A D^{-1}=\beta\left(\begin{array}{ccccc}
0 & 0 & \ldots & 0 & -\frac{p_{0}}{\beta^{N}} \\
1 & 0 & \ldots & 0 & -\frac{p_{1}}{\beta^{N-1}} \\
0 & 0 & \ldots & 0 & -\frac{p_{2}}{\beta^{N-2}} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \ldots & 1 & -\frac{p_{N-1}}{\beta}
\end{array}\right)=\beta \hat{A},
$$

Table 3: Results for polynomials $p_{N}(z)=z^{N}-i$. Times are measured in seconds. "Old" refers to the algorithm in [1], "new" to the algorithm described in the present paper.
where $\hat{A}$ is the companion matrix associated with $\hat{p}(z)$. Hence, the eigenvalues of $A$ can be easily recovered from the eigenvalues of $\hat{A}$ via multiplication by $\beta$. We will not go into details as to the most effective criteria for choosing $\beta$; here we are essentially interested in investigating the robustness of our method for different values of $\beta$.

The examples are mainly taken from [8], [4] and [2].

1. Wilkinson polynomial of degree 20: $p(z)=\prod_{j=1}^{20}(z-j)$.
2. Monic polynomial of degree 20 with roots [ $-2.1: 0.2: 1.7]$, in Matlab notation.
3. Monic polynomial with roots $2^{k}, k=-10,-9, \ldots, 9$.
4. Reversed Wilkinson polynomial of degree 20: $p(z)=\prod_{j=1}^{20}\left(z-\frac{1}{j}\right)$.
5. $p(z)=20!\sum_{j=0}^{20} \frac{z^{j}}{j!}$.
6. $p(z)=z^{20}+z^{19}+\cdots+z+1$.
7. Given an even positive integer $N$, define the complex polynomial (of

degree $N$ )

$$
p(z)=\prod_{k=-N / 2}^{N / 2-1}\left(z-\frac{2(k+0.5)-i \sin \left(\frac{2(k+0.5)}{N-1}\right)}{N-1}\right) .
$$

For comparison purposes, we also show errors for the Matlab routine eig applied to the companion matrix of the (unbalanced) test polynomials at points $1-5$. Observe that eig automatically performs balancing, whereas the column "eig nobal" shows results for eig with the balancing feature disabled.

Table 10: Results for polynomial 7.

These results confirm the robustness of our method under balancing.

## 7. Conclusion and Future Work

In this paper we have developed a novel implicit QR eigenvalue algorithm for companion matrices. The novel method is conceptually simpler and computationally faster than the one presented in [1], by preserving or even enhancing its numerical accuracy. In our opinion the algorithm using a compression technique is fairly optimized and a last final refinement would be to make simultaneous the double process of performing the QR iteration and reconstructing a minimal generator representation of the matrix returned as output. Experimental results are reported to show that the proposed algorithm behaves like a numerically backward stable method. The theoretical proof of backward stability is an ongoing research project. We are also planning to extend and use the compression technique for the design of fast QZ
iterations for dealing with structured generalized eigenvalue problems.
